PRINTED BY HAZELL, WATSON & VINEY LD., 52, LONG ACRE, W.C. 2, AND PUBLISHED BY THE PROPRIETORS,
AT THE OFFICES OF "THE LANCET," No. 423, STRAND, AND No. 1, BEDFORD STREET, STRAND.

MCMXXV.

INDEX TO VOLUME II., 1925.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (C.M.P.) = Conduct of Medical Practice, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, and (R. and A.R.) = Reports and Analytical Records.*

A Concordance of page numbers and dates of issue will be found at the end of the Index.

A

Abattoir Society, Model, B. W. Richardson Lecture at, 1042
Abdomen, The Early Diagnosis of the Acute (Zachary Cope), 3rd edit. (R.), 912
Abdominal adhesions, treatment of (W. Anderson) (M.T.T.), 32

THE

Croonian Lectures

ON SOME

DISORDERS OF MOTILITY AND OF MUSCLE TONE,

WITH SPECIAL REFERENCE TO THE CORPUS STRIATUM.

Delivered before the Royal College of Physicians of London

By S. A. KINNIER WILSON, M.D., B.Sc. Edin., F.R.C.P. Lond.,

PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE; JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

LECTURE I.*

Mr. President and Gentlemen,—It is my first duty to express to you, Sir, and to the Council of the College, the gratitude I feel in being honoured by the request to deliver the Croonian Lectures.

On not a few occasions within recent years the lecturer has selected a subject dealing with one or other aspect of the central nervous system, and for me the choice has been to some extent decided by the fact that for a long time the question of the possible functions of, and the diseases possibly to be assigned to, the corpus striatum has occupied my attention.

Twenty years have elapsed since there was admitted into the National Hospital under the care of Sir David Ferrier (whose house physician I then was) a young woman whose case proved to be the first adequately recognised as belonging to the group known as progressive lenticular degeneration, a disease in which unquestionably the most striking pathological feature is a disintegration of the corpus striatum. The impetus originally given to the study of this part of the brain by the work of a few observers abroad and at home has been vastly augmented during the last decade, till now the student of the subject is like to be bewildered by an unbelievably extensive literature, and has at his disposal a plethora of clinical material, due in major degree to the widespread occurrence of epidemic encephalitis and of sequelæ of that affection closely resembling paralysis agitans—a reputedly striatal disease.

Notwithstanding the abundant opportunities for investigation thus afforded, finality is far indeed from being reached in respect both of the pathology and the physio-pathology of the symptoms attributed to affections of the corpus striatum, and mere speculation is correspondingly rife. By way of a single illustration, motor symptoms as widely divergent as the complexity of an elaborate tic and the simplicity of a single muscle twitch or myoclonic contraction, as heterogeneous as palilalia and micrographia, are alike set down to striatal disease. Now, the corpus striatum is so situated that traumatic lesions are not calculated to produce any clear-cut picture of its symptomatology; its vascular supply is not derived from a single source; the morbid processes often involving its cell- and fibre-systems (e.g., that of epidemic encephalitis) are not restricted to the ganglia in question; the immediate vicinity of the corticospinal tracts sometimes renders it uncertain, in disintegration cases, whether there is not also concomitant interference with the function of these; even in Huntington's chorea, confidently regarded as a striatal affection because of the outfall of cells in the corpus striatum found with some frequency, every one knows that the cerebral cortex is also simultaneously implicated.

For these and a number of other reasons the ganglia situated in the base of the brain still, to a large extent, retain the characteristic of basements—viz., darkness. Since hypotheses erected on a still uncertain pathology have altogether outstripped clinical analysis, I have undertaken an objective investigation of various symptoms of a motor order some of which are assigned by many, on insufficient or erroneous grounds, as I shall endeavour to prove, to striatal disease. The need for further analysis along clinical lines is pressing, as will appear in the course of these lectures. The title has been deliberately chosen to avoid giving the impression, which might otherwise be gained, that the clinical phenomena to be considered are in my view and without comment to be set down to striatal disease and to that alone. This study, then, is concerned with the symptomatology of some affections commonly called "striatal," and with some types of movement commonly called "involuntary," as well as with certain problems arising therefrom.

The Syndrome of the Corpus Striatum.

In 1912, as a result of work on the disease to which the name of "progressive lenticular degeneration" was given, the following syndrome of the corpus striatum was put forward:

> "In pure, uncomplicated, bilateral lesions of the lenticular nucleus, and more generally of the corpus striatum, provided they are of sufficient size and of adequate duration, the clinical symptoms are bilateral involuntary movements, practically always of the tremor variety; weakness, spasticity, or hypertonicity (sometimes spasmodic contractions), and eventually contracture of the skeletal musculature; dysarthria or anarthria and dysphagia, and a degree of emotionalism; but without any sensory disturbance, without any true paralysis, and without any alteration in the cutaneous reflexes. If the abdominal reflexes are absent (apart from muscular rigidity), or the plantars of extensor type, then the syndrome is no longer pure."

While subsequent research has fully confirmed the general accuracy of this description, further investigation has filled in certain points then left more or less open, while in other respects, as we shall see, a more ingoing analysis of the symptoms then specified is now required.

In the same monograph the considerable resemblance between progressive lenticular degeneration and paralysis agitans was more than once alluded to, and approximate similarity of the pathology of the two conditions was reasonably surmised. This expectation is now known to have been correct, the essential pathology of Parkinson's disease consisting in degeneration of certain striatal cells and fibre-systems, and of parts of the efferent system of the same ganglion. Since progressive lenticular degeneration is comparatively rare, while Parkinson's disease and the Parkinsonian syndrome are common, we may take the latter as a working example of a mainly striatal malady.

During the last few years a tendency to schematic elaboration of alleged striatal symptoms on an ever-increasing scale has become an unreasonable feature of the literature of the subject, yet the cardinal symptomatology may still be summed up in three words: variability in muscle tone (dystonia), the appearance of "involuntary" movements, and the *seeming absence of "true paralysis."* As the last of these requires qualification and explanation, we may begin our study with it.

The "Voluntary" Motor System.

The term "voluntary," applied to movements, is in constant employment, but of elusive connotation. At a later point we may have opportunity to examine its meaning more closely; suffice it for the moment to say that "voluntary" movements are not *sui generis* in the sense of constituting a class apart; they are equivalent to "least automatic" movements, and all gradations may occur from "most automatic" to "least automatic." In objective characters they are not to be distinguished from other types of movement, equally coördinated and apparently purposeful, from which the element of "volition" is nevertheless awanting. No single criterion of an objective clinical kind (by string-galvanometer methods or otherwise) leads to differentiation; the "will" makes a subjective though not an objective contribution to a movement. Ordinarily speaking, we are in the habit of regarding as "voluntary" those movements which we have reason to believe are effected through the corticospinal or pyramidal tracts, to some extent because in the experimental animal movements (not, as a fact, strictly comparable to those of "volition") can be produced electrically via these tracts. The falsity of this deduction is apparent when we remember the ease with which movements can be electrically elicited from other paths never considered "volitional."

---

* Lectures II., III., and IV. will appear in subsequent issues.

Consciously, we are in complete ignorance of the specific muscular units effecting a "voluntary" movement. Consciousness knows only movements and terminal joint displacements produced by movement, and this has sometimes been taken to argue the representation of movements only in the cerebral convolutions. Evidence will be adduced later which, I believe, disproves the contention. The point at present is, that a very large part of every "voluntary" movement is both "involuntary" and outside consciousness. The expression "voluntary muscular contraction". must therefore be regarded more as a *façon de parler* than a term of differentiating quality.

Similar difficulties follow in respect of the term "paralysis," which is equally vague and open to misinterpretation. The clinician admits degrees of "paralysis," but would have hesitation in defining with precision exactly what they signify. In a given "voluntary" movement the elements of power of muscular contraction, appropriate coördination of muscular units, rate of contraction, accuracy of timing, estimation of amount of contraction required, are among some of the factors in the attainment of a perfect end, and if in any of these the voluntary movement falls short it exhibits in that respect a degree of "paralysis" or "paresis." *If a movement is normal except for its unusual slowness of accomplishment there is "paralysis" of normal rapidity of contraction.* When, in the definition of the striatal syndrome cited above, mention was made of the "absence of true paralysis," the intention was to endeavour to separate the "paralysis" ensuing on lesions of the pyramidal system from the recognised "motor helplessness" of extrapyramidal cases, in which, as was shown, objective signs of involvement of the pyramidal paths (absence of the abdominal reflexes, presence of the Babinski plantar responses) were awanting. It was then suggested that the discovery of an appropriate expression for extrapyramidal "paralysis" was a desideratum.

As it is, such terms as "weakness," "paralysis," "paresis," and even such apparently more precise expressions as "direct weakness of the motor impulse to the agonists" (Foerster), have, in fact, little if any specificity, however convenient they may be. If the word "paralysis" is indispensable, it may be justifiably employed to indicate imperfection of movement in respect of *any* of the components of a normal movement, and cannot be confined to questions of muscular strength or power alone.

It became apparent to me some time ago that in order to determine with certainty whether any particular kinds of movement were as a fact impaired or lost in disease of the corpus striatum a complete examination of the motor phenomena from the point of view of normal muscular action of various types would have to be undertaken. The reader of the literature of the corpus striatum will find himself confronted by statements as to loss of movements which in the absence of definitions or expositions are exceptionally confusing. Thus he will be told there is, inter alia, "loss of primary automatisms" (C. and O. Vogt), "loss of associated movements" (Foerster), "loss of individual movements" (Jakob), "loss of the associated movements that accompany voluntary movements" (Stertz), "loss of primitive automatisms and of higher coördinations" (Binswanger), "loss of (palæokinetic) automatic and associated types of movement" (Ramsay Hunt), and so forth. (I say nothing of the attempts to localise these and other motor defects in different sections of the ganglia in question.) Accordingly, a scheme of examination has been devised and applied to a large number of cases, mainly of the Parkinson group, but including also a typical case of progressive lenticular degeneration and a number of choreics of the Sydenham, Huntington, and senile varieties, as well as cases of athetosis. The terms used will be explained as they occur.

CLASSIFICATION OF MUSCLES IN A NORMAL ACT.

A physiological classification of the various muscles taking part in a simple movement of the type called "voluntary" divides them into the following groups: (1) Prime movers or agonists (protagonists); (2) synergic muscles, or synergists; (3) fixation muscles, or fixers; (4) antagonists.

This classification differs somewhat from those of Winslow and Duchenne, and follows the much more recent one of Beevor. For simplicity's sake it may be modified to include (2) and (3) under the one heading of synergists. Thus in the elementary illustration of the movement for closure of the fist the agonists or *prime movers are the flexors of the fingers and thumb*; the synergists are the extensors of the wrist, while the antagonists are the extensors of the fingers. Beevor showed that in firm closure of the fingers the triceps and biceps act as fixation muscles when a certain measurable degree of contraction of the agonists is attained, and regarded the "fixation group" as *fulfilling an essential part in all movements* in distinction from the synergists, which he defined as "the muscles which are brought into the combination when a prime mover has, by passing over two or more joints, two or more actions of which only one is required; the synergics are the muscles which neutralise these undesired actions." In the above-given example the synergic muscles, the wrist extensors, serve to obviate flexor deviation of the wrist by the contracting long finger flexors, hence in reality their function is one of fixation. It is practicable, therefore, to include as synergists such muscles *as contract (invariably or variably) either to fix joints* other than that, or those, actively engaged in the particular movement required, or to enable the prime movers to execute their function with a maximum of effect.

Using the attribute "synergic" in this specific way, I do not speak of "synergic movements" or "movement synergias." In a *whole* movement *part* only is synergic; I shall not use the term to express a complete movement, or a movement concurrent with another. The necessity of this restrictive definition becomes apparent in view of the meaninglessness of any wider application. All the units in a voluntary movement coöperate, even though some may constitute a "coöperation of antagonism," as Hughlings Jackson might have said. If synergy is synonymous with coöperation it is otiose. There is the more need for terminological clarity at this point in that Tilney, whose contributions to a difficult subject deserve respectful consideration, appears inclined to employ the term "synergic unit" to include *all* the muscular components in a given movement—thus eliminating the muscular distinctions drawn above. For the present, however, it will be convenient to keep closely to a classification which has definite clinical merit.

"VOLUNTARY" MOVEMENT IN STRIATAL DISEASE.

(1) *Strength or Weakness of Movement.*

The customary clinical tests of muscular power have been employed in this connexion. They lack absolute value, but they possess considerable relative value if carried out by an examiner of experience, whose subjective standard is based thereon. Various rather elaborate methods have been devised to establish a scale of strength; the only apparatus I have employed has been the dynamometer, the same instrument *always being used, and in two ways—either by a* succession of grips first on one side and then on the other, or by alternate right and left grips. The most useful information has been obtained by selecting unilateral Parkinsonian cases, care being exercised rigorously to exclude those in which pyramidal function was not considered normal.

For illustration only three cases need be cited.

1. *Left-sided unilateral case.*

Consecutive.		Alternate.	
R. 150	L. 101	R. 145	L. 100
141	110	140	100
130	100	140	105
131	111	130	103

2. Right-sided unilateral case.

Consecutive.		Alternate.	
R. 82	L. 98	R. 71	L. 101
81	92	62	90
84	90	83	82

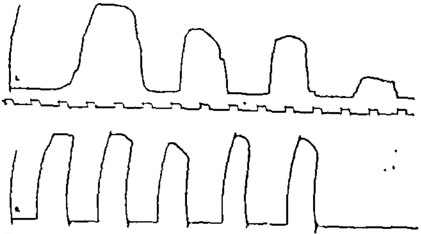
3. Bilateral case.

Consecutive.		Alternate.	
R. 72	L. 48	R. 52	L. 40
65	45	65	42
72	38	42	15

From an analysis of many similar records and a comparison with normal cases the disparity between the two sides in unilateral cases is clearly greater than can be accounted for by the natural right- or left-handedness of the individual concerned, and, also, in bilateral cases the reduction of power, as estimated by the dynamometer, is unmistakable. *The conclusion is that relative motor weakness is to be expected in striatal cases of the Parkinsonian type, varying within wide limits but definite enough.* This is in accordance with the experience of James Parkinson himself, who, in his celebrated "Essay on the Shaking Palsy," mentioned in his definition the occurrence of "lessened muscular power."

Another point brought out by dynamometer records concerns the question of progressive weakening in a series of similar movements. This is stated to be a characteristic of striatal affections, but my observations do not substantiate it; at least, not without some qualification. A glance at the above figures will show that in the unilateral instances similar movements (hand-grasping) are at first relatively better sustained on the *affected* than on the unaffected side. Only, however, *for a few* consecutive "voluntary" movements is this usually found; in a longer series the affected limb undoubtedly tends to weaken more than the other. This is in accordance with the remark of a right-sided Parkinsonian girl, who said: "I could hit anyone hard with the right hand several times quickly, but I couldn't do it slowly, or keep it up." If the arm is actively flexed against resistance at the elbow it eventually tires more readily than the normal. Successive movements of supination and pronation against resistance exhibit a similar tiring. If the patient stands and swings the extended arm in a wide circle from the shoulder reduction of the extent of the swing is eventually visible on the affected side in comparison with the other.

FIG. 1.



Case of unilateral (left) Parkinsonism. "Voluntary" contractions of right (lower tracing) and left (upper) quadriceps.

A good way of demonstrating the same phenomenon is by placing the patient in the recumbent position and getting him to make single consecutive "voluntary" contractions of the quadriceps group on the front of the thigh. The action of gravity is excluded and there is no displacement at the joint concerned, since he is requested not to lift his heel off the couch. From Fig. 1 it will be seen that on the right (normal) side the patient was able to make five successive "voluntary" contractions of the quadriceps in slightly over 11 seconds, the last being as good as the first; on the left (Parkinsonian) side there were four contractions in 12 seconds, and they exhibit a progressive reduction in extent, much more noticeable, however, in the fourth than in the first three. Another tracing from a less severely affected patient (Figs. 2 (A) and 2 (B)) shows five quadriceps innervations ("as quick as you can") in five seconds, all of normal amplitude, as compared with five in eight seconds, very limited in extent, on the affected (left) side.

FIG. 2 (A).

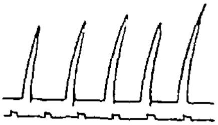


FIG. 2 (B).

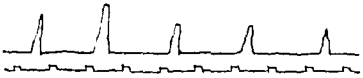


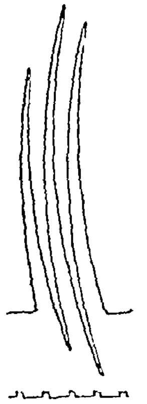
FIGS. 2 (A) and 2 (B).—Another case of unilateral (left) Parkinsonism. "Voluntary" contractions of right (A) and left (B) quadriceps.

The records from a well-marked case of unilateral Parkinsonism furnish clear evidence of similar weakness in respect of the "voluntary" movements of the long flexor of the forefinger (Figs. 3 and 4). On the right (unaffected) side the tracing reveals a free, quick, and wide movement of the finger, three consecutive and smoothly coördinated innervations taking place in less than three seconds. By comparison, three similar movements of the left forefinger ("crooking" of the finger) are very slow, extremely limited, and irregular, requiring no less than 17 seconds for their completion.

Among the movements particularly apt to exhibit weakness are those of separation of the fingers (interosseal). The Parkinsonian cannot readily "spread" his fingers, feebleness and a certain lack of precision being often seen; nor can he approximate the tip of the thumb and that of each of the other fingers in a quick, strong, and precise fashion. Abduction of the little finger is not infrequently almost nil. Movements of the tongue, too, both inside and outside the mouth, are especially prone to exhibit the same characteristics. It is protruded very imperfectly, and is not infrequently "bitten" in the course of mastication. Speaking generally, the defect is chiefly seen in small-muscle movements, those of larger muscular masses being less obviously imperfect, one reason for which may be simply that gradations of movement are more easily followed by the clinical eye in small than in large muscles, and minor variations of power more easily estimated (see also below).

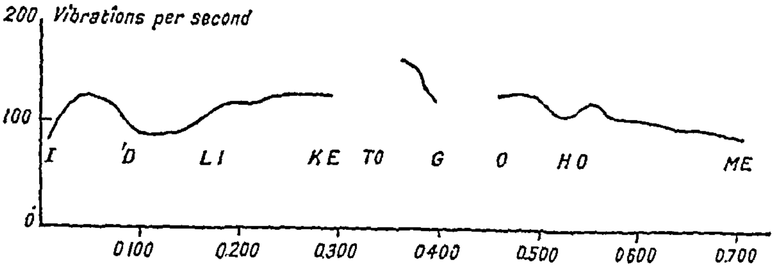
A further example of this imperfection of "volitional" movement in the smaller muscles is provided by those concerned in phonation and articulation. A common feature of the phonation process in paralysis agitans, progressive lenticular degeneration, and other striatal syndromes is the "mono-tonous" voice. *Parkinsonians* are compelled to give up singing. As Brissaud said, these patients lose "le chanson du langage," the inflections and modulations which characterise normal pronunciation. Their vocalisation is one long *monotone*. I asked Prof. E. W. Scripture to take records for me, one of a normal voice and one of a severe case of Parkinsonism selected for the purpose. The latter, I believe, is the first record of the kind that has been taken. The striking differences between the two can be realised by comparing Figs. 5 and 6. The sentence enunciated in each instance was "I'd like to go home," and while in both the duration was approximately 0·7 seconds, the record of the Parkinsonian is distinguished by complete absence of flexibility, measured in vibrations per second. In other words, here is evidence of imperfection of "voluntary" movement in a well-defined physiological group of small muscles, revealed by defect of range and of flexibility at a quick rate (that is, the record reveals the presence of muscular rigidity). To dissociate the quotas of these elements may be somewhat difficult, but in so far as they constitute a departure from normal "volitional" movement of the apparatus in question, they indicate a degree of motor "paresis" in the sense specified above.

FIG. 3.



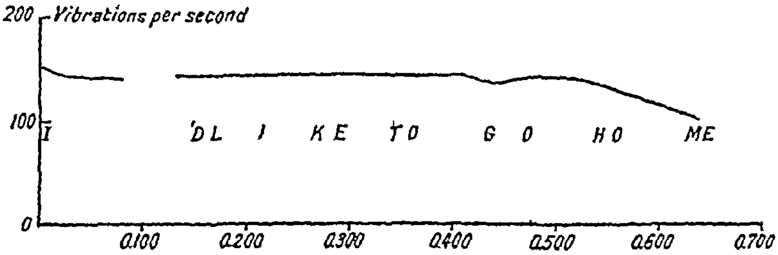
Case of unilateral (left) Parkinsonism. Normal "voluntary" contractions of right long flexor of forefinger.

FIG. 5.



See explanation in text.

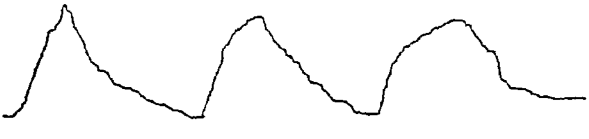
FIG. 6.



See explanation in text.

Reference may now be made to the ocular muscles. While as a general rule the external ocular muscles of the Parkinsonian are supposed to exhibit no motor abnormality, in a large number of instances a "punctuate" movement of lateral conjugate deviation is seen. The eyes move in a somewhat jerky fashion with fractional pauses at intervals in the course of the deviation. Such "punctuate" movement is, however, by no means confined to cases of the kind we are considering. In some respects it partakes of the *nature* of the "cog-wheel" phenomenon described below, and is probably to be assigned rather to a disorder of muscle tonus than to weakness of innervation. A more interesting observation is one that has long been a commonplace—viz., defect or failure of convergence. A high percentage of cases of paralysis agitans (and in this respect it is obviously advisable to deal for the moment only with idiopathic cases) reveal inability to converge, one or other eye usually swinging out, or at least failing to move inwards, at the appropriate moment. In one case the patient remarked spontaneously that one of his earliest symptoms was inability to light his cigar, since he could not with accuracy bring the lighted match to the end of it—a convergence-accommodation defect. Peripheral paresis of the internal recti being excluded by the normal participation of the muscles in other ocular combinations, we have here a fairly definite "paralysis" of a specific synkinesis or movement-combination—viz., that of *the above extrinsic muscles with the ciliary muscles* and the sphincters of the irides. (This synkinesis is unusual in that it comprises a union of somatic-motor and viscero-motor elements, but the fact that the sphincter iridis is phylogenetically a striate muscle must not be overlooked.)

FIG. 4.



Same as Fig. 3. Slow and limited "voluntary" contractions of left forefinger (affected).

Of its occurrence more than one explanation is possible.

In elderly folk the convergence-accommodation mechanism naturally tends to functional involution, but apart from this, its "paresis" occurs in Parkinsonians who are not old in years, while the symptom may be observed in post-encephalitic Parkinsonism as *a solitary ocular defect, the peripheral visual* apparatus being in other respects normal. Here, evidently, is a loss of a particular movement of a set of muscles with preservation of other movements of the same muscles. Hughlings Jackson held there are differences of "evolutionary rank" of movements of the same muscles, and, regarding convergence-*accommodation as a very "special"* movement, was rather at a loss to account for its retention in ordinary hemiplegia. Curiously enough, he does not appear to have viewed its bilaterality as an explanation for that pyramidal disease; he came, rather, to the conclusion that "convergence, as it has to do with distances, belongs to the *locomotor series (cerebellum)* and not to the tactual series (cerebrum)." His inference was that the movements of convergence are chiefly represented along with movements of the spine, arms, and legs for locomotion. Distance appreciation is doubtless connected with locomotor functions, but any supposition that the Parkinsonian failure of convergence is linked to the locomotion disorder is perhaps rather far-fetched, interesting though such a speculation may be. In a special series of observations I have been unable to satisfy myself that precisely those cases with convergence defect exhibit the most noteworthy disturbance of the "locomotor series." Be this as it may, the frequent impairment of the mechanism under consideration provides *further proof of weakness of "volitional" movement in striatal disorder.*

Weakness of closure of the eyes is fairly often encountered, especially in post-encephalitic cases. The patient *appears unable to "screw the eyes up tightly"*; the orbicular muscles usually pass into a *state of blepharospasmic trembling. If the eyes are* in fact closely shut *for a moment or two he not infrequently seems to be unable to maintain the voluntary* contraction tonically. The orbicular muscles of the mouth may act in a *similar fashion*; the Parkinsonian tends to have his mouth *open or his lips apart*, and *cannot always "purse them up" strongly*, as does the normal individual. *If he does, he cannot always maintain the tonic contraction.*

I attach no little importance to this *weakness of maintenance of contraction*, which, for that matter, can be demonstrated also in other small muscle movements, and is found (as I have shown) in cases of progressive lenticular degeneration as well. It furnishes proof of the inaccuracy of the common statement that Parkinsonian movement is always *characterised* by slowness of relaxation. *Further*, it is a *clinical* symptom the very opposite of that imagined by some to be typical of extrapyramidal disease—viz., so-called "perseveration" or "tonic innervation." I shall return to this question at a later stage.

As far as movements at large joints are concerned weakness is much less noticeable. *Movements of* trunk, head, and proximal limb segments against resistance are sustained with no little force, nor is restriction *of range as a* rule in evidence, at least contrasted *with that of* small muscles. *I have never* seen actual *loss of movement of a big joint in* Parkinsonism such as *may be observed* in any recent and severe hemiplegia, or, of course, in any paralysing lesion of the lower motor neurone. If the patient's limb is passively put into a position half-way towards that which he is *asked to assume actively, it will often be found to execute the movement* with greater power. Thus, if with leg fully extended he is required to flex at the knee, he will accomplish the movement more forcefully should the knee be first passively flexed to a right angle. Foerster appears to claim this phenomenon as an alleged peculiarity of striatal affections, but it is in reality a question of mechanical leverage—the adoption of an optimum position no less characteristic of normal musculature than of diseased.

To decide whether in the striatal affections exemplified by paralysis agitans and its congeners any predilection type of "paralysis" or "paresis" obtains, as we know is the case in pyramidal affections, we have at our disposal data of the varieties illustrated above, and *the general conclusion seems justified that those musculatures whose mass is small are found to exhibit feebleness of "voluntary" contraction, and that, for the body as a whole, this feebleness is in inverse ratio to the size of the muscle or muscles concerned.* A generalisation of this description, however, should not be taken too literally or mathematically, though I *believe it to* be clinically applicable.

We have seen that in regard to laryngeal, interosseal, *facial*, glossal, ocular and other small musculatures the contention seems substantiated. In respect of *their* movements there is found in a large number of instances such lessening or reduction *of range*, flexibility and quickness of contraction, such fatigability, such imperfect maintenance of contraction (*in some instances*) as constitute a definite enough "paresis" or "paralysis." When a hemiplegic patient *slowly* and laboriously extends his fingers we do not hesitate to describe the movement as "weak" or "paresed," and no adequate reason can be advanced *for refusing the same descriptive epithet* to the slow, laborious, and limited "*spreading*" of the *Parkinsonian fingers. Dynamometer records* prove the existence of muscular weakness in moderately *severe striatal cases, hence the non-specificity* of the term "paralysis" already alluded to.

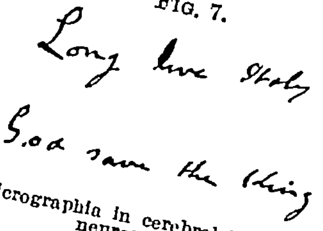
With *the exception of the ocular musculature*—where the defect is largely if not entirely confined *to the convergence-accommodation* mechanism—the small muscles in the distributions mentioned above *are weak for all movements.* They are muscles implicated in the execution of the most delicate of acquired *movements, especially so in the case of* fingers and phonation-articulation apparatus (larynx, tongue, lips); *muscles in which fractional gradations* of innervation are essential for the production of the finest changes, *as in speaking and in* precise and exact finger movements. This highly special class of acquired "voluntary" *movement, then*, suffers more than any other in diseases of the group in consideration, and offers in this connexion *no essential* difference from what obtains in pyramidal cases, except, it may be, *in regard to the speech* muscles. These are less likely to suffer in hemiplegia, owing to their bilateral *innervation. Consonantly* with this, unilateral Parkinsonian cases may exhibit little speech—i.e., *phonation-articulation*—disorder. The loss of highly specialised, recently acquired movements which Hughlings Jackson *thought so* characteristic *of* hemiplegic cases is paralleled by their impairment in *Parkinsonian cases.* One has only to observe the Parkinsonian *fumbling* with his buttons or his necktie, or *to ask his* patient whether he is still able to shave himself, *to be assured* of this. (Since the *advent of the safety razor* the argument has been rather "side-stepped.")

The cause or causes of the motor impairment exemplified in this *section* will be more conveniently discussed *after certain other* features of the "voluntary" nervous *system* in striatal disease have been examined.

Micrographia.

Under this same heading of "Strength or Weakness of Movement," the behaviour in paralysis agitans of the fine acquired movements of writing may be appropriately considered. The disturbance of movement known as "micrographia," described years ago by Arnold Pick, but recently resuscitated and alleged to be characteristic of striatal affections by Bernhard, Bing, and others, and indicative of actual paresis by Foerster, deserves remark. The symptom has interested me ever since the appearance of Pick's original paper in 1903 and long before attention was directed more specifically to the corpus striatum. The condition consists, as its *name* implies, in an obvious reduction in *size of the lettering of the* writer in comparison with his calligraphy before the development of the organic lesion affecting the change. It is writing in miniature. According to my own observations a distinction should be *drawn* between the micrographia which is *as* obvious at the beginning of a sentence as at its close, *and that* which consists rather in a telling *off into a smaller* lettering because of fatigue or other *inability to maintain* the range voluntarily. In respect of the former variety (to which perhaps the term *might be restricted*) in my experience *it is certainly neither confined to striatal cases nor in any sense pathognomonic of them.* Bernhard commits a *petitio principii* by *confining* his researches to cases in which striatal *disorder has been* evident or presumed. On the contrary, it may be observed in typical form in hemiplegia and *other corticospinal* conditions. For example, the writing reproduced in Fig. 7 is that of a patient who *developed a right* brachial monoplegia of cerebral *syphilitic origin*, from which a good degree of recovery *was made. He* was a professional mandolin player and complained *of two* residual symptoms: (1) he had lost all facility in making the fine movements of striking the mandolin strings with his "plectrum," though otherwise he could use the arm with ease; (2) since the "stroke" his handwriting had become unaccountably small in comparison with his previous style. The loss of the acquired movements of "plectrum"-striking constitutes a limb-kinetic apraxia in Liepmann's sense and definitely suggests a cortical origin for the disorder, while the concomitant and otherwise entirely monosymptomatic micrographia can legitimately and confidently be assigned in this case to disturbance of cortical function. From a case of cerebral arterio-sclerosis the writing seen in Fig. 8 was obtained. It was that of a patient with slight right hemiplegia and slight defect in speaking, and had been noticed since the onset of the right-sided weakness some months previously. No trace existed of the arterio-sclerotic muscular rigidity often assigned (by Foerster and others) to striatal disease, nor any symptom of a kind that could be referred to the ganglion. On the contrary, the evidence pointed to implication of the cortex in part of the distribution of the left sylvian artery.

FIG. 7.

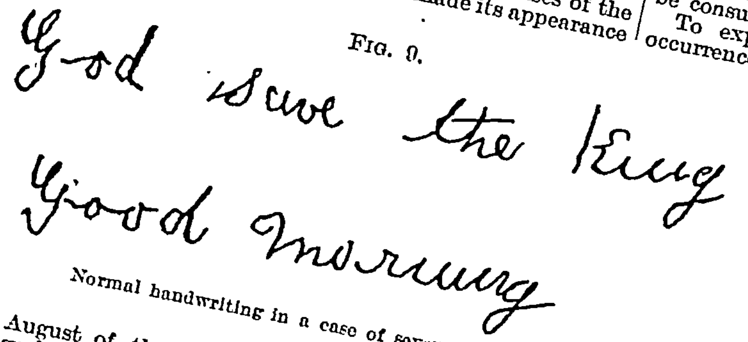


Long live Italy
God save the King

Micrographia in cerebral (cortical) neurosyphilis.

Taking next actual Parkinsonian cases, I have seen many in which severe striatal (or assumed to be striatal) symptoms have been unaccompanied by any micrographic disorder. Thus, the handwriting reproduced in Fig. 9 comes from a typical case of post-encephalitic Parkinsonism of an aggravated sort, the patient being one of the most immobile and rigid I have so far observed. When he was being tested with the dynamometer he did not reveal by a single muscular flicker otherwise the strong effort he was making with his right or left hand, but his calligraphy shows no departure, as far as size goes, from his previous normal. By way of contrast, however, the most pronounced micrographia in my collection is that of a lady who came under observation only a month or two ago, one of the encephalitis cases of the spring of 1924. Her Parkinsonism made its appearance in August of the same year, and her micrographia is such as to render her writing almost illegible (Fig. 10), yet, otherwise considered, the symptom-complex in her particular case is of only moderate degree.

FIG. 9.



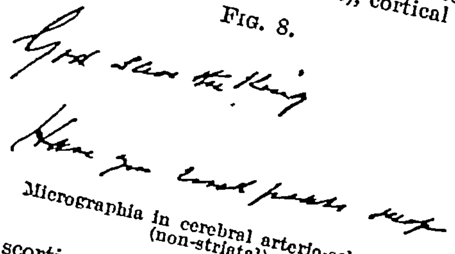
God save the King
Good morning

Normal handwriting in a case of severe Parkinsonism.

For the understanding of this difficult and somewhat involved subject preconceived ideas as to the function of the corpus striatum or its symptomatology in diseased states must be avoided. Micrographia should not be divorced either from its opposite, macrographia, or from the frequent concomitant of macropsia or micropsia. As far as I have noticed, Bing only of recent writers refers to these, solely, indeed, to macrographia, which he calls "megalographia," and thinks is of cerebellar origin. He uses the illustration as an argument for the existence of symptomatological opposites between striatal and cerebellar disease. Recent contributors to the subject have quite failed to take into consideration the variety of cases in which micrographia may occur, and its not infrequent connexion with disorders of vision and of the muscular sense.

In a paper read in 1916 at the Congress of the Ophthalmological Society of the United Kingdom, and published in their Transactions, numerous instances were adduced of the association of micrographia or macrographia with the visual disturbance of dysmetropsia—the term proposed for departures from the normal either in the minus (micropsia) or the plus direction (macropsia)—and the occurrence of this visual defect at peripheral (lowest), cortical (middle), and transcortical (highest) levels was fully exemplified, cases of hysteria, migraine, and cerebral tumours, of tabes dorsalis and disseminated sclerosis, &c., being selected for the purpose. With these clinical data before us, all that need now be said is that in cortical and transcortical conditions micrographia may be an accompaniment of macropsia, and, *mutatis mutandis*, macrographia of micropsia; or, alternatively, either variety of calligraphic defect may occur without visual disorder (as in the cases cited above). Again, micrographia often is met with where muscular rigidity is insignificant, as in some examples already given, and it may be seen in other instances where kinæsthetic factors have come into play. This latter association is of peculiar interest, for further details in regard to which the paper above referred to may be consulted.

FIG. 8.

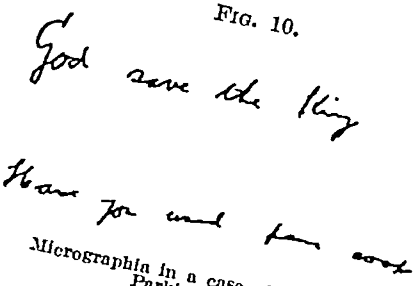


God save the King
Have you had peaceful sleep

Micrographia in cerebral arterio-sclerosis (non-striatal).

To explain its admitted, if far from constant, occurrence in paralysis agitans and post-encephalitic Parkinsonism, the following questions have to be answered: (1) Is it of transcortical, cortical, or subcortical origin, and (2) is it connected or unconnected with accommodation disorder? To take the latter first: Nearly all of the Parkinsonians with micrographia that have come under notice have exhibited impairment of the convergence-accommodation mechanism, but none of them has complained of the visual disorder I call dysmetropsia. Now our estimation of size can be shown to be regulated mainly by (1) retinal images and retinal disparation, (2) accommodation and convergence "effort," (3) certain psycho-physical factors (distinctness, relative size, light and shade, &c.). Paralysis or paresis of accommodation is often stated to be accompanied by micropsia, and spasm of accommodation by macropsia, but in innumerable instances I have satisfied myself that patients with one or both eyes under the influence of atropine are not aware of any dysmetropsic defect, and, further, in many cases of

FIG. 10.



God save the King
Have you [illegible] [illegible] [illegible]

Micrographia in a case of moderate Parkinsonism.

complete ophthalmoplegia externa and interna no such impairment is remarked. Besides, it is easy to show that in organic and non-psychical cases macrographia, not micrographia, is to be expected with micropsia. For these reasons one cannot feasibly link the micrographia of Parkinsonism to any defect of convergence.

As for the former of the questions stated above, an analogy from this same visual field is apposite. In different individuals the retinal image, retinal disparation, the *kinæsthesia of accommodative effort* (if there is such a thing), and the psychological factors already referred to briefly are all prominent in widely differing degrees, in the determination of the depth or distance of a visual object, and so of its size. Hence micropsia may result from lesions at one or other of three neural levels or, quite possibly, from lesions involving more than one. In a not dissimilar fashion we may discover the elements producing micrographia to have their anatomo-physiological site at one or other of the same three levels, or at more than one. Accordingly, we must take into account the possibility, as far as concerns Parkinsonian micrographia, of (1) infracortical disorders such as rigidity of antagonists; (2) central ("middle level") dysfunction, such as disturbance of pyramidal innervation for fine acquired movement; (3) "highest level," "transcortical" impairment, such as absence or diminution of the "will" to act, or the condition usually described as dyspraxia. Without further discussion in this place, enough has been said to prove that cortical and transcortical components may have as definite a share in the "lilliputian" symptom under review as those of lower level origin, and that *acceptance of the striatal theory, in any exclusive sense, is quite impossible.*

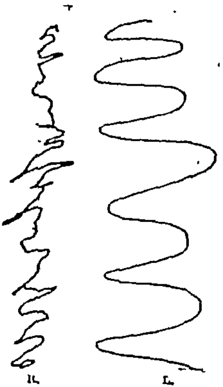
(2) *Beginning, Course, and Cessation of Movement.*

That the Parkinsonian is "slow off the mark" is matter of common observation. Recent measurements with special apparatus for muscular response to a single visual stimulus have given the figures of 0·21 seconds for normal individuals and 0·30 seconds for the subjects of paralysis agitans. With the comparatively simple recording methods which I have utilised myself the feature of slowness in starting and continuing movement has been abundantly exemplified (cf. Figs. 1, 2 (B), and 4). If the patient is at first able to make movements of practically normal rapidity ere long he becomes conscious of retardation. Thus in a well-marked unilateral (right) case the patient made a series of wheel movements of the extended right arm from the shoulder. For three or four complete revolutions the movement was normal, but it then became distinctly slower, the subject remarking spontaneously "it seems to require more effort of my will"; becoming ever slower, the revolutions ceased at the tenth time, whereas on the left they could be kept up indefinitely. Both in a clockwise and counter-clockwise direction the phenomena were similar. Slowness is so conspicuous a feature of all movements of the "volitional" order that it scarcely requires further illustration. It is none the less a variable feature. Apart from the fact already mentioned, that earlier movements may be accomplished in better time than later, the reverse occasionally is encountered, the rate improving slightly after one or two innervations. In all the actions of daily life, dressing, eating, &c., every Parkinsonian admits his unwonted delay in accomplishment. The "drag" is such as on occasion to bring volitional activity almost to a temporary standstill. Coupled with the retardation is a restriction in range and excursion to which allusion has already been made several times, and which is well exemplified in Fig. 11.

In a large number of cases, however, this slowness is more apparent than real, and is so declared to be by the patient himself. The characteristic slow, shuffling, and limited gait, reminiscent of the "démarche à petits pas" or brachybasia of the "lacunaire" or double hemiplegic (in which cases on occasion incidental involvement of the basal ganglia may occur), can be modified in a surprising fashion if the observer puts his arm inside the other's and invites him to step out. The brachybasia may then easily disappear. A member of our profession, suffering from paralysis agitans, made the curious remark to me that he found he could walk more quickly over the stones of a rocky sea-beach than on the flat, the reason probably being that he was compelled to take longer steps. Parkinsonians often run better than they walk, in this respect presenting an illuminating contrast to tabetics, in whom inability to run while still able to walk is an early sign I have frequently observed. They enter the out-patient room and come to the table with a little run. I have seen a subject of advancing paralysis agitans tuck up his feet and sprint along a garden path when progression at a walking pace was painfully slow. Another patient was actually able to proceed backwards, uphill, at a greater speed than forwards and on the level. James Parkinson gives a graphic description of more than one case in which "the inability for motion, except in a running pace, appeared to exist in an extraordinary degree." As a rule, this power of modification of an apparently hampered musculature is seen more in respect of the lower than of the upper extremities—a corollary, it may be, of the fact that the "voluntary" movements of the former are more, the latter less, "automatic." A remarkable circumstance connected with not a few cases of post-encephalitic Parkinsonism has been the variability in slowness and motor range-reduction at different periods of the day or night, at the instance of extrinsic or intrinsic stimuli, the action of which is far from being clearly understood. (In this connexion similar variability has been reported by one or two writers as taking place under the influence of hypnosis, but I am not in a position to add any personal contribution on this point. Improvement or disappearance of Parkinsonian micrographia under hypnosis has also been recorded.) At a hospital recently I saw a girl, suffering from typical and severe post-encephalitic Parkinsonism, who lay immobile in bed and whose movements in response to my requests were characteristically slow and laboured; yet I was assured her nurses had accidentally discovered that if she was "dumped" up and down on the bed several times in a sitting position she then was able to get up and walk round the ward normally! In the idiopathic disease such peculiar variability is far less in evidence, but if we connect the changeableness in movement described above for the idiopathic patient with the curious though rare phenomena of the post-encephalitic patient, we can only suppose the symptoms to depend less on structural lesions than on dynamic alterations of function, that from time to time innervation is facilitated by modification of the background of muscular hypertonus against which it is ever contending, that the tendency to "involuntary" contraction of the antagonists transiently relaxes. To these matters we shall return later. At any rate, we must concede the possibility of fluctuations in the muscular state greater than a glance at the seemingly immobile attitudes might lead us to imagine.

As for cessation of "voluntary" movement, my observations lend no support to the view according to which the muscles in action in Parkinsonian cases

FIG. 11.



Case of unilateral (right) Parkinsonian. Freehand to-and-fro movement of pencil from above down; L, normal; R, affected side.

may remain tonically contracted, perhaps for seconds, after the "voluntary" impulse has ceased. In no case have I been able to satisfy myself that any condition strictly analogous to "tonic innervation" occurs. By the latter expression is understood inability to decontract, to order or on a signal given, a "voluntarily" contracted muscle or group of muscles. Tonic innervation is of central origin, in the sense that the cases of it I have seen, and those reported by others, have all been due to cerebral lesions, but as far as the actual symptom of inability to relax a contracted muscular group is concerned, no clear clinical distinction can be drawn between it and the phenomenon commonly denominated myotonia. No criterion exists by which to judge when a contraction, "voluntarily" commenced, is prolonged sufficiently to be specified as "tonic," except that if it is maintained beyond the command to relax it is *ipso facto* pathological. Thus understood, tonic innervation in a mild form occurs in many morbid states (moderately severe hemiplegia, athetosis, &c.), but in my experience the phenomenon is so uncommon and uncertain in Parkinsonism as to be practically negligible. If the reader will look at Figs. 15† and 18, taken from cases of advanced bilateral post-encephalitic Parkinsonism, he will find proof of this. In one case, that of a young woman, voluntary action involving the hands and fingers was feeble and tremulous and rather limited in range, but after sustained "voluntary" contraction of the long finger flexors ("close the fist") and, synergically, of the wrist extensors, at the word "open" the long finger extensors instantly contracted and the wrist extensors instantly relaxed—that is to say, neither protagonists (prime movers) nor synergists exhibited any trace of tonic innervation (Fig. 15). In this respect the behaviour of the muscles is identical with that seen in any normal individual (Fig. 14). Similar records have been obtained for the action of trunk and neck prime movers, as well as for trunk synergists in arm movements (cf. Figs. 17 and 18).

(3) *Poverty of Movement.*

The term "poverty of movement" (Bewegungsarmut) has come into vogue to express the familiar symptoms of relative immobility and stationariness of position which are particularly characteristic of the subjects of the shaking palsy. No greater contrast can be imagined than is afforded by the akinesis of the latter, especially in the variety known as paralysis agitans sine agitatione, and the universal fidgetiness of the subjects of chorea. The Parkinsonian scarcely if ever manifests spontaneity in change of position; he literally "sits still." I have for a long time now been impressed by the fact that the average Parkinsonian never sits with his legs crossed, whereas nothing is more frequent in the normal individual than a seated position with one knee over the other. Glancing round the benches at my clinic at King's College Hospital one afternoon, I found 10 out of 20 students sitting in this way. Similarly, the Parkinsonian never sits with his arms folded, though here again is a commonplace change of attitude adopted frequently enough by the normal person. In a score of ways the absence of initiative, of spontaneity, of normal muscular play impresses itself on the observer. Among men a particularly common movement occurs in the course of ordinary conversation—viz., a movement of the hand and fingers to the chin, lips, and lower part of the face, but I have never yet seen a patient with paralysis agitans who has thus raised his hand. Women have a favourite "spontaneous" movement in similar circumstances—viz., toying with their wedding or other ring, but Parkinsonians do not do so. No changing expressions of emotion flit over the face—again providing a striking contrast with what obtains in chorea. This last remark raises an interesting point. Doubtless "spontaneous" movements contain "volitional" and "automatic" elements in inverse proportions—i.e., they are largely "automatic" and but faintly "voluntary"; on the other hand, change of position frequently results from the action of peripheral stimuli that certainly reach the sensorium, hence a conscious, "volitional," factor is not to be entirely excluded. But emotional expression is essentially "involuntary," so that in the patient with Parkinson's disease we note the absence, or poverty, *both* of "voluntary" motor action *and* of "involuntary" motor action, at least as far as the expression of the emotions is concerned. I attach importance to this conclusion, and since a "corresponding opposite" in encountered in cases of chorea the point will be referred to again.

Allusion was made above to variability in the course of Parkinsonian movement from time to time, and a similar variability characterises this "Bewegungsarmut." On occasion, especially in post-encephalitic cases, the patient appears to exhibit more freedom of movement than at others, and the ordinary "spontaneous" motions of everyday life are more in evidence. From patients of sufficient intelligence and introspection it is possible to gain some insight into the causation of their motionlessness, for I may say at once I consider the subjective factors of no less importance and significance than the objective.

CAUSES OF PARKINSONIAN AKINESIS.

(1) The general akinesis seems to me explicable largely by deprivation of, or serious reduction in, normal impulses to movement, both of the "voluntary" and the "spontaneous" kind. When asked, patients will admit the reduction of the need for or impulse to muscular action. Their "will to act" is impaired. They say in so many words that movement requires a greater effort of the will than previously. Everything is done "with an effort." And the curious thing is the rarity with which they seem to wish to make such efforts; on the contrary, they appear to contemplate this defect of motor function with a philosophical resignation. Those afflicted with the disease complain more of "losing the use" of their limbs, of loss of muscular power and of capacity for executing the ordinary fine movements of every day, than of mere "sitting still." We have seen that they can, as a fact, if they will, perform most of the movements of which superficially they appear incapable, but since this puts a tax on "effort" they simply do not make them.

Spontaneous change of position or posture being mainly a response to peripheral impressions, it may be designated a movement of reaction—a sort of "psycho-" reflex movement, for consciousness is probably faintly stirred. To these sense-impressions the Parkinsonian and the senile (for a similar decrease in motility is natural to the senescent) are alike indifferent, probably for more than one reason. In the case of the former, no evidence suggesting an afferent origin for the impairment is forthcoming; the peripheral nervous system on the sensory side all agree is normal. A questionnaire addressed to a number of intelligent Parkinsonian patients has elicited the answer that they rarely "feel the need" to change position, and this might conceivably be taken to argue for an actual reduction in afferent stimuli, owing to the relative fixity of the limb musculature. The muscles, however, are, many of them, in a condition of contraction; they are not "resting" or relaxed, immobile though the patient be; hence their sensory end-organs must be receiving stimulation. On the other hand, afferents from articular and periarticular tissues are probably to some extent restricted, but I cannot think this has a material bearing on the problem. That the immobility-effecting disturbance of function is not sensory receives support from another consideration.

Akathisia.

There are patients in whom immobility is actually a prominent symptom and yet who complain in a paradoxical way that "they cannot sit still," or only "with an effort." After a time they simply must get up and walk about, immobility having become intolerable; they say they feel "all strung up," or "tightened and screwed up," and so on. In other words, they feel, as does the normal individual, the cramping effect of an unchanging posture and have to move and stretch their limbs at intervals; the accumulation or summation of afferent excitations, derived from a largely motionless (though not resting) musculature, is such that the patient must rise and "work it off," only, however, to sink once more into the same state of motionlessness. Since, then, incoming impressions exist, the reduction of spontaneity in movement must have its origin on the effector side. Since I commenced to observe this phenomenon in the course of my studies more particularly of the last two years, I find that Bing has directed attention to it, and employed the term originally devised by Haskovec—"akathisia"—for cases of inability to "sit still" of hysterical or psychasthenic origin. Bing refers to various authors who have noted akathisia in paralysis agitans and post-encephalitic Parkinsonism, and while not committing himself to one explanation only, seems inclined to accept the view which some others have adopted and which is in accord with that here given. In my opinion akathisia is only an exaggeration of what is seen in normal individuals, and, since it has a psychogenic basis in some instances, it cannot be ascribed in any exclusive fashion to striatal disorder.

---

† Figs. 14, 15, 17, and 18 will appear in Lecture II.

At this stage a word of caution must be entered as to indiscriminate use of the term *loss of movement* in connexion with Parkinson's disease. I have studiously avoided using the term "loss," apropos of reduction of voluntary and spontaneous movement, because I do not consider that the movements are in fact "lost" (with the few exceptions, and these only in part, already mentioned). *Because a patient does not make a movement it does not follow that he cannot.* It is of importance to bear this in mind when we discuss the functions of the corpus striatum at a later point.

(2) As for reduction of "voluntary" activity, the totality of sense-impressions at any given moment being in the Parkinsonian not much different from that of the normal person, we cannot ascribe the inaction to failure of extrinsic stimuli, although these doubtless play a part as one of the springs of action. Intrinsic stimuli, at whose bidding the "voluntary" motor system passes into activity, may perhaps have an ultimate sensory origin, but we cannot express this "impulse" in physiological terms; we know only that our patients say they are not as conscious of it as formerly. It is idle, therefore, to speculate whether such intrinsic stimuli are damped down centrally by a process of inhibition which rarely lifts, or are not forthcoming in adequate amount, or not endowed with sufficient potential. Perhaps this potential has an affective quality, and the "affect-quantum" essential for an impulse to generate action may be awanting. Apart from considerations of this kind the Parkinsonian knows from experience that voluntary movements are no longer effortless and facile, and desists *largely of his own accord.* Even in respect of this "sense of effort" not a little is obscure. Binswanger, for example, declares that in paralysis agitans "innervation-feeling" is lacking, yet what is signified thereby is not clear. We have already noted the absence of any sensory impairment in the disease, and cannot liken the motionlessness to that of the anæsthetic limb, all of whose dorsal spinal roots have been severed experimentally, as shown by Mott and Sherrington. Nor can "feelings" arising in the course of muscle innervation be lost; Parkinsonian muscles are not at rest. Besides, it is uncertain whether, and to what extent, kinæsthetic impressions can really exercise a stimulant effect, or their relative diminution result in immobility. Once more, no evidence is available to indicate that motor or efferent currents are themselves sensed. According to Titchener, "there is no such thing as a motor-cell sensation, a sensation corresponding to the innervation of a muscle or group of muscles," though Hughlings Jackson himself maintained that "the outgoing current, a motor cerebral current, is concerned with the physical processes during referrings of sensations to parts of the body"—in any case a view of little bearing on the present point. "Innervation-feeling," therefore, or rather its absence, offers no explanation of the phenomena. I suspect that by a "sense of effort" the patient signifies little else than the consciousness that his muscles no longer "answer," as the rudder "answers" the helmsman's lightest touch at the wheel; and *the conclusion, as indicated already more than once, is, that some at least of the akinesia of the Parkinsonian is the direct outcome of unwillingness to move, since the making of movement is no longer effortless.*

(3) The objective state of the peripheral motor apparatus is without doubt a factor, yet only one, in this general akinesia. No constant relationship between degree of peripheral rigidity and decrease of spontaneous or "voluntary" movement can be established, for the reason that the motor phenomena under discussion are frequently found where muscular rigidity is not a conspicuous feature. Relative immobility of facies and of limbs is often an early symptom in the disease, sometimes the earliest, before rigidity makes itself obvious. One of the earliest indications of the onset of the Parkinsonian "mask" is notable infrequency of ordinary blinking movements of the eyelids, but in other respects facial movements, "voluntary" and emotional, may still be normal, no trace of rigidity in any facial group being detectable. Reference has not as yet been made to the characteristic attitudes of limb segments in the disease, but it may be remarked here that they develop more or less *pari passu* with the immobility—i.e., it is an immobility in attitude or posture. Now no constant interrelation obtains between rigidity and attitude in the first instance, for the hands and fingers may assume attitudes involuntarily at an early stage when the corresponding muscles are not demonstrably rigid.

As the disease advances, however, a general tendency to muscular fixity becomes ever more obvious, implicating all skeletal groups more or less indifferently. It is due mainly to a hypertonic state of the musculature, an overaction of the tone-effecting apparatus, to which due attention will be devoted subsequently. As a consequence, when the innervating current of "volition" reaches the motor periphery, it finds that: (1) The muscle elements it would innervate are already in relative contraction; (2) the antagonists to the required movement are also in activity. At this stage we shall not pursue the analysis further, for the matter can be more conveniently dealt with in the sections on disorder of muscle tonus. My observations, however, will show that in spite of the background of muscular overtone "voluntary" innervation can accomplish its ends both as regards prime movers, synergists, and antagonists in a given movement, so that *the conclusion is permissible that the condition of the peripheral motor system is no more than one of the causes of Parkinsonian akinesia, and not necessarily the most important.*

We must beware in Parkinsonian cases of attributing to disease of the corpus striatum symptoms not in fact pathognomonic. A limb may be immobile, or relatively immobile, (1) because the lower motor neurones are "paralysed," as in poliomyelitis; (2) because there exists a combination of innervation weakness and muscular spasticity, as in hemiplegia; (3) because presumably normal innervation encounters a "block" in distal motor mechanisms, as in paralysis agitans (in part); (4) because central "impulses" are awanting, as in the same disease. Under (4) should be included, for the sake of completeness, certain cases of psychosis (catatoniac stupor, anergic stupor, &c.), in which the immobility is psychogenic and partakes of a negativistic character. *In short, akinesia, or poverty of movement, obviously may arise at one or more of lower, middle, or highest physiological neural levels (in Hughlings Jackson's sense), a possibility which renders invalid its ascription to the corpus striatum alone.* Failure to envisage ætiological differences in respect of the development of this symptom, as with others that have already been made the subject of investigation, has been a fruitful source of confusion; with the exception of Binswanger, most recent continental writers have over-emphasised the "hypokinetic-rigid" syndrome of the *corpus striatum* at the expense of other clinical conditions of which immobility is a symptom, but which are in no way associated with striatal disease.

(4) Somewhat similar explanations must apply to the general slowness, retardation, and limitation of "voluntary" movement in the disease, as well as to the muscular weakness. Here again a wide conception is indispensable. Allusion was made above to the "motor helplessness" of the subjects of paralysis agitans and of progressive lenticular degeneration, and in my original monograph on the latter disease the facts were fully exemplified. I found that "volitional movements may be good in range, but they are usually resisted with comparative ease. This muscular weakness is not to be confused with clumsiness or awkwardness from hypertonicity or tremor. There is *intrinsic muscular asthenia*; the patient is incapable of any sustained effort; he cannot close his eyes tightly for any length of time, cannot keep his tongue protruded, cannot maintain his grasp." At that time I endeavoured to avoid the use of the term "paralysis," hoping it might be confined to diseases of the pyramidal system. Further consideration has led me to modify this hope, for *quâ* weakness, limitation, slowness, I see little material distinction between hemiplegic and Parkinsonian cases. The differences between pyramidal and extrapyramidal cases are distinct enough, but not as regards the above points. The *general* approximation of cases of double hemiplegia, especially of the pseudobulbar variety, to cases of paralysis agitans sine agitatione was emphasised long ago by Hughlings Jackson and again by Brissaud, and in these recent years we have seen examples of post-encephalitic Parkinsonism in which the diagnosis from pseudobulbar palsy has been more than a little difficult.

Having demonstrated the existence, in numerous instances, of such weakness, slowness, and imperfect range of "volitional" movement as constitutes, in Foerster's words, an "unmistakable paresis," I do not agree with him that there is no predilection type. On the contrary, a special class of acquired movements—viz., those of the smaller muscular groups throughout the body—is particularly liable to be affected, as has already been fully exemplified. *The small muscles* are those employed in what James Parkinson called "any nicer kind of manipulation"; their failure "to answer with exactness to the dictates of the will" is their characteristic in more than one state of motor defect. As a class, they suffer more than any other in hemiplegic cases; derangement or outfall of fine finger movements is seen in hemiplegia, and of laryngeal, glossal, facial, and ocular movements (it may be) in double hemiplegia. In extrapyramidal, as in pyramidal cases, analogous but not necessarily identical imperfection of small movements is to be observed. It is true, as we have seen, that in some instances seemingly as definite "paralysis" of various small muscle activities characterises Parkinson's disease, as it does pyramidal disease: but no one considers the pyramidal morbid state the replica of the other. The rigidities are not identical, nor are the "paralyses"; when, however, we find general resemblances in the types of movement that suffer, we are entitled to seek an explanation that is physiological rather than anatomical. In other words, *I do not take the "weakness" of certain movements in striatal affections to imply a concomitant anatomical defect of the corticospinal system, or of similar movements in hemiplegia to be the sequel merely of the corticospinal interruption; in each case the movements are disordered because their physiological quality or character is such that they suffer most and earliest.* To account for the "weakness" in paralysis agitans Foerster postulates a second corticomuscular path passing through the globus pallidus and in simultaneous action with the ordinary corticospinal tract in "voluntary" innervation. To me this hypothesis seems completely unnecessary (apart from its anatomical dubiousness); the rigidity in Parkinson's disease is *general*, but the "weakness" is *special*, and I submit the latter cannot be accounted for merely by anatomical interruption, just as in hemiplegia the special type of motor defect cannot be the outcome merely of a haphazard interference (by hæmorrhage or otherwise) of an anatomical system. In each instance there is defect or loss of *some* movements; in each the same *sorts* of movement are disturbed: behind both instances, therefore, must lie a similar disorder of function, but it is not a similar disorder of structure.

ORGANISATION AND WORK OF A LIGHT DEPARTMENT IN A HOSPITAL FOR SURGICAL TUBERCULOSIS.*

By Sir HENRY GAUVAIN, M.D., M.C. Camb.,
MEDICAL SUPERINTENDENT, LORD MAYOR TRELOAR CRIPPLES' HOSPITALS AND COLLEGE, ALTON AND HAYLING ISLAND, HANTS; CONSULTING SURGEON (TUBERCULOSIS) TO THE LONDON, ESSEX, AND HAMPSHIRE COUNTY COUNCILS.

Though I have used lamps for light treatment for many years, and indeed had three German quartz mercury-vapour lamps in regular use for a considerable time before the war, it is only since the cessation of hostilities that I have been able to realise a long-cherished wish and have a properly planned and staffed light department. The great interest recently displayed in light treatment and the many requests I receive for assistance from practitioners and institutions desirous of installing apparatus for light treatment are my apology for this sketch of the organisation and work of the light department at Alton.

It may be of some help to those contemplating introducing light treatment into institutions which they serve or administer if I quite briefly outline the reasons which impelled me to establish a light department at Alton and the steps I took to plan and organise it.

Artificial Light Treatment.

First let me state that in this paper by light treatment I mean treatment by light produced by artificial means as opposed to sunlight. The term artificial sunlight I dislike as slovenly and misleading, and though the mercury-vapour lamps I have already alluded to were called artificial mountain suns, I have still to discover any lamp to which such a title can be legitimately or wisely given.

Though light treatment has been extensively scientifically investigated, especially during the last few years, it should be remembered that it owes its origin to shrewd clinical observation and its justification to clinical experience. Fascinating as are theories endeavouring to explain the biological action of light, they still remain incomplete, are sometimes contradictory, and are frequently confusing. Many and wide gaps in our knowledge still remain, and I recognise fully that the scientific principles of light therapy still rest on an incomplete and not too stable basis. I shall therefore confine myself here entirely to practical considerations.

Very considerable opportunities for the practice of sun treatment on an exceptionally extensive scale, both inland and at the seaside, had convinced me of its value in surgical tuberculosis. It was, therefore, natural that one should wish to employ light derived from artificial sources therapeutically.

The Light Department Introduced at Alton.

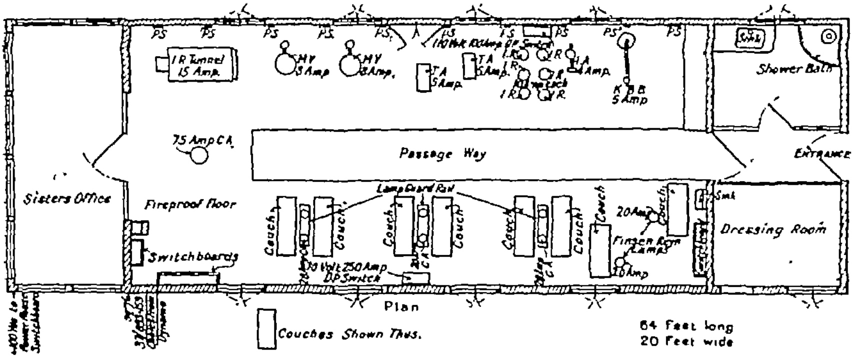
The cessation of hostilities, the sympathetic approval of the late chairman of the hospital, Sir William Treloar, and the generosity of a private subscriber, gave me the long-desired opportunity of founding a light department.

---

* A paper read before the Electro-Therapeutic Section of the Royal Society of Medicine.

It is apt to be forgotten by those contemplating artificial light treatment on any considerable scale that *this form of treatment* is *necessarily very expensive*. The initial purchase of the lamps is only the beginning and not the end of considerable expenditure. Much electric current must be consumed, the services of a skilled electrician are essential, the plant must be maintained and renewed, experimental work is almost essential, numerous accessories must be purchased, a staff of nurses must be trained, retained, and maintained. Indeed, the lamps are the least expensive item. Needless to say, this side of the matter was carefully and anxiously considered. I had to satisfy a generous but astute business man in the person of Sir William Treloar, on whom devolved the burden and the responsibility of financing the hospital, that in the interests of the patients under my care the expenditure contemplated, and which would be a constantly and probably increasing drain on the institution, was essential, unavoidable, and justifiable. I would emphasise this aspect, for I am convinced that at this stage an *elaborate* light department is neither essential nor justifiable for many institutions.

FIG. 1.



Ground plan of the Light Department. Couches are indicated on the carbon arc (70-volt) side: they are not shown on the 110-volt side. The iron arc, Kromayer, and Finsen-Reyn lamps are water-cooled; the water, circulating through these lamps, discharges into the sink. P.S.=10-ampère plug and switch. I.R.=Infra-red ray lamps. I.R. tunnel=Radiant heat (luminous rays) tunnel. M.V.=Mercury-vapour lamps (air-cooled). T.A.=Tungsten arc lamps. D.P.=Double-pole switches. K.B.B.=Kromayer type of water-cooled mercury-vapour lamp. C.A.=Carbon arc lamps. I.A.=Iron arc lamps.

The success which had attended sun treatment gave promise of success from artificial light and made its employment justifiable, the impossibility of obtaining certain results except by artificial light made it essential, and the natural course of evolution in a progressive institution made the establishment of such a department unavoidable. I had absolutely convinced myself of the need before I attempted to influence Sir William Treloar. No hospital for surgical tuberculosis in the country had a properly equipped and staffed light department. For lupus cases especially such equipment was an urgent need. Its value has been thoroughly demonstrated by Dr. Sequeira at the London Hospital, whose brilliant results in the treatment of lupus are so well known. There was no shadow of doubt that numerous cases demanded the treatment a light department alone could give. By the system of heating already employed all the electricity required for the light department could be generated free of cost other than fair wear and tear of the machinery. There already existed an admirable generating plant and a highly skilled and competent resident engineer who could install and maintain the new plant required without additional cost to the institution, and conduct the necessary experimental electrical work requiring investigation.

The next point to determine was whether a new building for the light department should be erected. Here I felt that it was a safe assumption to make that further possibilities exist and much further investigation is needed. Finality has *not* yet been reached, and therefore the present light department has been created in an adapted ward which could readily be spared. The present light department must therefore be regarded as probably needing modification and possibly considerable extension at an early date, but, when the time comes for further extension, no building will have to be scrapped, and the ward will revert to its original purpose. Such apparatus as remains of proved utility will simply be transferred to a specially designed building. Meanwhile we are acquiring at a minimum cost experience which will be available later. (Figs. 1 and 2.)

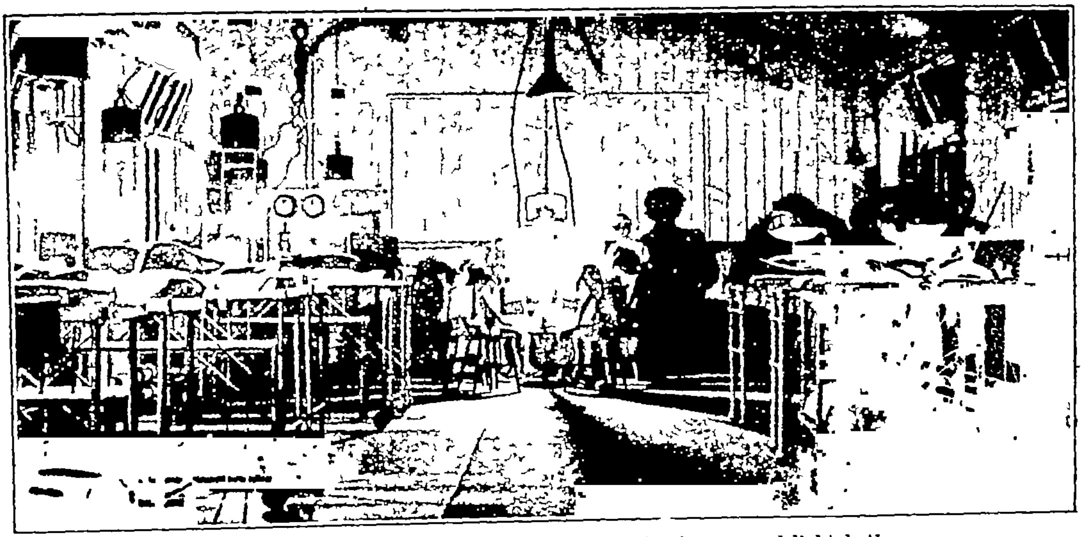
A ward was therefore selected as near as possible to the power-house to reduce the cost of cable. The ward is a simple wooden structure. The necessary cabling, wiring, and installation of the lamps was done by direct labour. To reduce the risk of fire the walls to a height of 4 feet and the floors were covered with sheets of asbestos, which has the advantage of being cheap, non-inflammable, a non-conductor of heat, and, in addition, has a dull non-reflecting surface, so that the patients and staff are not subjected to eye-strain by reflected light. In the power-house a motor generator was erected to break down our existing voltage of 110 to 70. In the trench dug two cables were laid, one to convey the current at 70 volts, the other current at 110 volts for lamps other than the Danish. Each has a main double-pole switch, where it enters the light department, so that the whole current can be instantly switched off in the light department as well as in the power-house should occasion require it. Necessary switchboards with ammeters and voltmeters, fuses, and abundant plugs for the 110-volt circuit are, of course, fitted. All the fittings, metal couches for recumbent cases, and even the mattresses on which the patients lie were made in the institution.

These essential preliminaries having been settled the nature of the installation to be provided and the means to be adopted for training the staff had to be considered.

The Finsen Institute, Copenhagen.

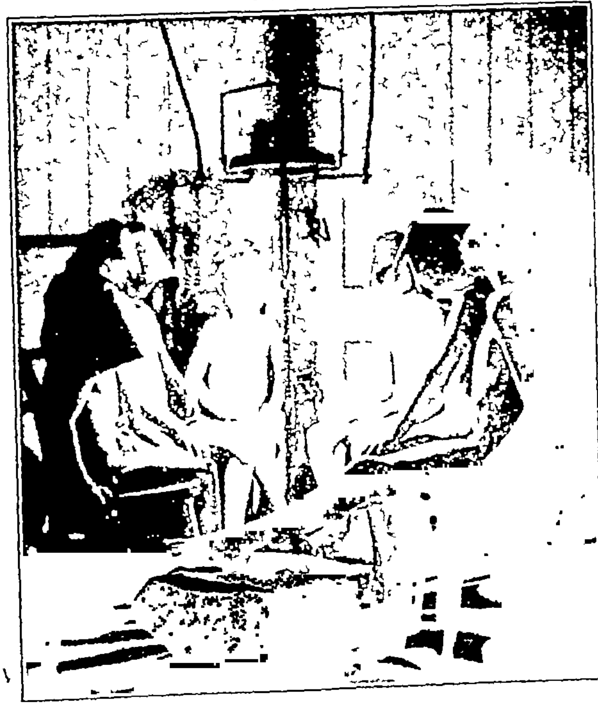
Naturally, the first place to turn to was the Finsen Institute, Copenhagen, and it appeared to me essential to make myself as fully conversant as possible

FIG. 2.



One end of the Light Department. Patients having general light baths.

FIG. 3.



The 75 ampère carbon arc lamp.

with the methods of phototherapy employed in this pioneer and famous institution. By the kindness of Dr. Axel Reyn, the director, I was permitted to visit the Finsen Institute and study its methods under his guidance. I would here like to express my gratitude for and appreciation of his generous kindness. He took infinite pains in instructing me in the admirable technique he employs. No detail was too trivial, no difficulty too great. I have the most profound admiration for the technique followed at the Finsen Institute, and the success which has been achieved there is a tribute to its thoroughness. The technical skill which has been employed in designing the lamps used, the exact care with which they are used, the ingenuity displayed in the application of the light in difficult cases, the meticulous cleanliness devoted to the lenses and applicators, the perfect drill, the splendid team-work, and the high degree of perfection of the carbons used as electrodes—these and other details aroused my sincerest admiration. I found that Dr. Reyn and his co-workers pinned their faith to the carbon arc for both the general light baths and for local treatment. General light baths with the carbon arc had been used at the Finsen Institute systematically and with success since 1913. The majority of the cases treated were lupus vulgaris. Dr. Reyn has shown that by combining general light baths with local treatment speedier, better, and more certain results were obtained. The use of general light baths was extended to other forms of tuberculosis, but lupus remains the most common form treated.

A second visit confirmed the favourable impressions derived from the first, and I determined that a large part of my light department should be based on the teachings of the Finsen Institute. I followed these to the best of my ability, modifying them where necessary for my particular needs, and copying them carefully where exact imitation was desirable. But another point was firmly impressed on me as the result of my visits. To obtain similar results it would be necessary to have identical apparatus and to employ identical technique. I must have not only carbon arc lamps, but carbon arc lamps as used at the Finsen Institute with Finsen carbons as electrodes, Finsen ideals of thoroughness, and genuine Finsen technique. To secure the last Dr. Reyn kindly arranged that one of the most competent of his trained sisters, a highly educated lady who spoke English fluently, should come to Alton to instruct the nurses in our light department, and, in addition, I arranged for one of our sisters to work at the Finsen Institute in Copenhagen. In each case the visit was of six months' duration and particularly competent sisters were selected. The result of this has been thoroughly satisfactory.

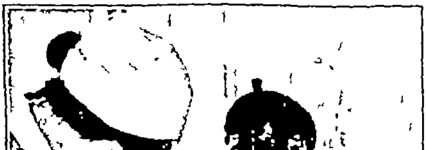
The installation obtained from the Finsen Institute was as follows. Two 75 ampère carbon arc lamps, each capable of treating eight ambulant patients simultaneously; six (i.e., three pairs) of 20 ampère carbon arc lamps for recumbent patients, and three water-cooled Finsen-Reyn 20 ampère carbon arc lamps for local treatment. With such an installation and by following rigidly the adopted technique, I felt confident that successful results could be anticipated. and that confidence has been justified. At the same time I felt that I must not limit my phototherapy to one particular method. Accordingly, I decided to make provision for testing and employing where desirable any other form of light which seemed of promise

During the last few years much attention has been paid to ultra-violet radiation, and especially to short-waved ultra-violet rays. Their value in rickets has especially been abundantly demonstrated, their tonic action has attracted much attention The discovery that the bactericidal power of the blood might be raised after exposure of patients gave alluring prospects. Indeed, the tendency has recently been to use short waved ultra-violet rays more and more, excluding or reducing the use of the longer-waved rays

Many so-called artificial sun lamps are rich in short-waved rays never found in the solar spectrum Makers will often point with pride to lamps which will produce a full erythema dose in three minutes. Such lamps are indeed attractive They are comparatively cheap, consume little current, have most striking and rapid action, are therapeutically very active, exceedingly short exposures are alone needed and can be tolerated, and they are very easily installed Accordingly, on my 110 volt circuit I made provision for these, and regularly continue to use mercury vapour, tungsten arc, iron arc, and other lamps In addition, I have tried several other lamps and numerous electrodes. Many of these have their uses, some are very valuable, especially in certain local conditions, but, on the whole, in surgical tuberculosis, at any rate, they have not come up to expectations. For solid clinical results, as far as I have observed them, I find myself more and more reserving them for the treatment of certain local conditions or even for certain stages in the evolution of local conditions. I admit their value, but had I to choose between them and the various types of Finsen lamps I should at the moment unhesitatingly select the latter.

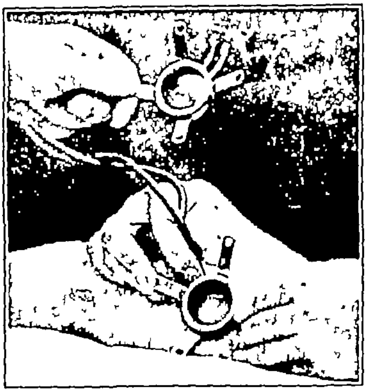
While many important investigations on the mode of action of light have been completed in the laboratory the subject is so complex, so many factors are involved, that I believe clinical experience is still our most reliable guide. When we consider the matter further, this attitude appears to me to be logical. The short-waved rays have very little penetrative power, but have a powerful superficial necrotic action, so that long exposure cannot be tolerated The total radiant energy introduced into the patient is therefore comparatively small Caution should be exercised in their use, and the existing tendency to employ them indiscriminately is not devoid of danger. I do not wish to speak dogmatically, for I fully appreciate the value of these rays in many conditions—in some, indeed, their action is remarkable, as, for example, in relieving acute neuritis of undiscovered origin. How these short-waved rays have acted I cannot tell, but the fact that they have given almost instantaneous relief remains. Nevertheless, until we know more about their mode of action my whole instinct is to be cautious in their employment.

FIG 4.



Finsen Reyn lamp.

FIG. 5

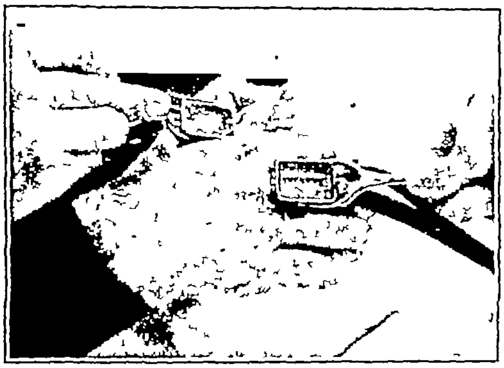


Applicators for treatment over muscular areas—e.g., limbs.

This leads to a very important matter in connexion with light treatment On the physical side it is possible to produce almost infinite varieties of radiant energy, and to use these rays in a variety of combinations. But while many observations have been made of their biological effects there is so much more to learn that just as you need a bacteriologist or pathologist for ordinary hospital routine so, it appears to me, you need a skilled laboratory worker in connexion with your light department. By the combined generosity of Sir Horace Plunkett and the Medical Research Council I have been able to secure such help in connexion with my light department, and we are fortunate in having obtained the whole-time services of Dr Bannerman, at Alton, for this purpose in the first light laboratory established in connexion with a hospital in this country. He is checking, investigating, and assisting us by every means in his power, and his work is proving of the utmost value The result of his observations will be the subject of communications from time to time

With regard to the actual work of the light department, I have planned arrangements somewhat differently from the Finsen Institute Experience in the administration of a large children's hospital has taught me the importance of constant and complete responsible supervision As you will see from the plan, the whole of the light department is visible and readily accessible. There are no cubicles, recesses, or separate treatment rooms, so that the sister in charge has everything always under her eye. In my opinion certainly children and generally adults should never receive light treatment unless under constant trained observation. Children may endanger themselves by playing, they may be faint or sick, they may interfere with and infect exposed wounds, some mishap may happen to the lights, or some unforeseen event may occur. If the ideal of trained supervision is realised, then separate rooms for separate lamps or special treatment are impracticable unless expense is no object. With children the necessary supervision is comparatively easy. The older boys or girls attend at different sessions. With adults separate sessions for each sex would also be observed or the light department duplicated. At Alton patients are treated behind screens only when their condition is such that privacy is essential, as in such conditions as lupus of the vulva receiving local light treatment.

FIG. 6.

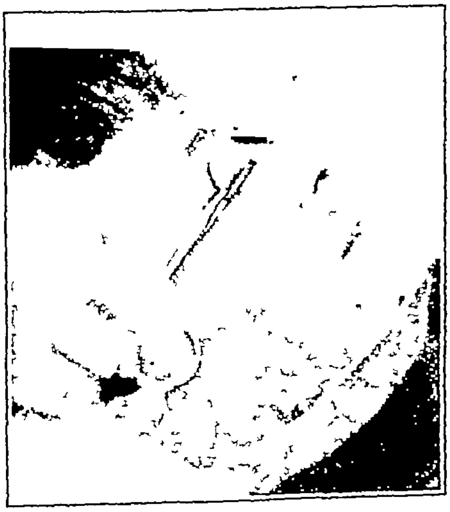


Oblong concave and convex applicators for digits or inter-digital spaces.

Two sisters-in-charge are therefore employed. At the busiest period of the day both are on duty. The nurses come on duty at 7.30 A.M. Actual treatment commences at 8 A.M. Local light treatments proceed continuously from that time with the Finsen-Reyn, tungsten, iron and other arcs, and the mercury-vapour lamps, until 7 P.M., with intervals for dinner and tea.

At the conclusion of treatment the department is thoroughly cleaned out, all lamps examined, the Finsen-Reyn lamps completely dismantled, each lens individually cleaned, every compressor similarly treated, and everything made ready for the following day. General light treatments with the carbon arcs are held daily from 9 till 11.30 A.M., and from 1.30 till 4 P.M. At each of these sessions six recumbent and eight ambulant patients are treated, so that 28 patients have general carbon arc light baths daily. I agree entirely with the experience of the Finsen Institute that two and a half hours on alternate days is ample for general light baths for individual patients. Fifty-six patients, therefore, are having such light baths every other day. That is usually sufficient for present requirements. If more general light baths with the carbon arc are needed, an additional session must be held or general light baths with other lamps be given. One 75-ampère arc is always held in reserve and may be used to give supplemental light treatments if needed. (*Fig.* 3.)

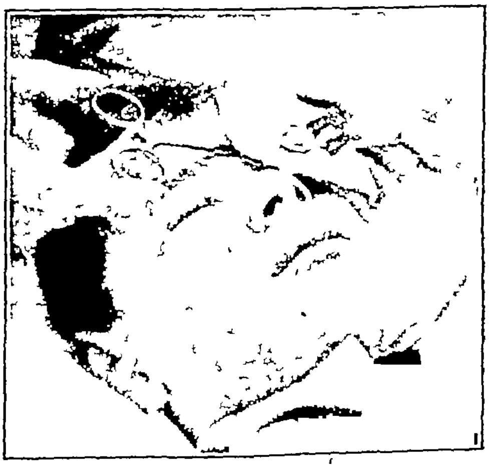
FIG. 7.



For treatment on the under surface of an eyelid. The eyelash is clipped by specially designed forceps.

Each patient having a general light bath is provided with a special simple brown paper shade for his eyes; this is cheaper, safer, and much more sanitary than goggles. Each member of the staff has his or her own goggles; convenient specially designed lorgnettes are used for occasional visitors. Each patient is also provided with a clean bathing slip, a clean face towel and bath towel for each treatment, and, in addition, ambulant patients have their own wooden sabots, which are scrubbed after use. During treatment patients are given water to drink. As *a general rule, exposure of half an hour per session* is given to new patients, increasing from one-quarter to half an hour per session to a maximum of two and a half hours. Ambulant patients face the light, sitting the first half of the session; during that time they frequently amuse themselves by singing or conversation. When their backs are exposed they are permitted to read. They sit as near to the lamps as the heat will permit, the nearer the better, as it will be remembered that the intensity of the light varies inversely as the square of the distance from its source. The current used is a direct current, the positive electrode is above; on the under side of that electrode an incandescent crater is formed, *the light is thus thrown down on to the patients* with minimum wasted diffusion. During treatment free perspiration occurs, and at the conclusion of treatment each ambulant patient proceeds to the douche room, where he is sprayed with tepid water, dried, and dresses in the dressing-room. Recumbent patients are washed on their stands after treatment, dried, and returned to their wards suitably clad. The sheets over their mattresses are removed and replaced by clean ones before each session. There is thus a considerable amount of laundry work inseparable from light department routine. Recumbent patients are irradiated on conveniently movable stands which we specially constructed at Alton. Adjacent stands are exchanged at half-time during each treatment, and patients are turned so that

FIG. 8.



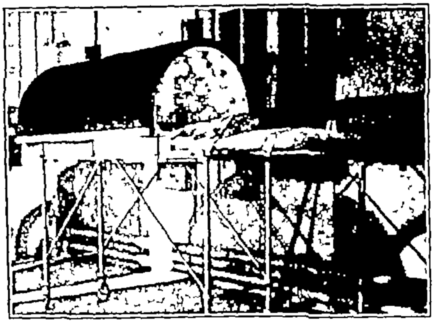
Applicator in position over everted eyelid.

each part of the body is equally irradiated, the patient's head being protected from the heat by adjustable asbestos shields. For recumbent treatment three 20-ampère lamps are needed for each two adults, two for each two children.

The Finsen-Reyn lamps (Fig. 4) are only used for the local treatment of lupus. Success with these lamps depends largely on the skill of the operator and the exercise of scrupulous cleanliness. Great attention is therefore paid to training selected nurses in their use. Nurses are not allowed to use these lamps until they have served three months in the light department and shape well. They are then given progressively difficult lesions to treat. Specially designed compressors are used for different regions of the body, as will be seen from Figs. 5 and 6. These compressors, of varying shapes and sizes appropriate to the part being treated, are each constructed of two pieces of clear quartz mounted in metal. In the space between each piece of quartz, cold water is in continuous circulation while treatment is in progress, during which time the compressor is kept firmly in apposition with the part being treated. The light from the Finsen-Reyn lamp is derived from an automatically-fed scissor-shaped arc, and is focused through a cylinder containing five quartz lenses. This tube, which is filled with pure distilled water, filters off most of the heat rays, and this filtration of heat is continued when the focused light is transmitted through the water-cooled compressor to the lesion. The distilled water in the cylinder is cooled by tap-water kept continuously circulating around it. These lamps are kept continuously in use, with the exception of Saturday and Sunday afternoons, Bank holidays, and during part of the month of August, when the light department is closed down. Fresh distilled water specially prepared and free from particulate matter is put in each cylinder daily. In addition to renewals, as occasion arises every lamp is completely overhauled at regular intervals. Treatment with the Finsen lamp usually occupies two hours for each area treated, but that varies to some extent according to the part involved. Thus, treatment of the under surface of the cocainised eyelid rarely is practicable or desirable for more than 20 minutes. (Figs. 7, 8.)

By the use of quartz compressors which exsanguinate the part treated much deeper penetration of the light is possible. The light appears to have a selective action on the infiltrated tuberculous tissue. An intense reaction occurs in the area treated, which lasts for several days, exceptionally weeks, and further local treatment on that spot is not repeated until the reaction subsides. It is of very great value indeed in the majority of cases to intermit the light baths after a period of treatment, this period varying with different patients. If the light baths both general and local are abandoned, say, for about a month and then resumed they are much more effective. Not only is this done, but the patients are then given the advantage of complete climatic change, scene and régime, as I have found that it is of surprising benefit to send the majority for this rest period to Hayling Island. Here during the summer months they may have particularly valuable natural sun treatment, immensely enhanced in suitable cases by graduated sea-bathing. I must not dwell on this point, but I cannot sufficiently emphasise its value. The effect on both the general health and the local lesion is marked.

FIG. 9.



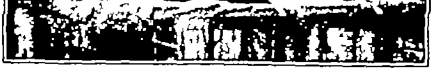
The tunnel: Radiant heat lamps (tungsten and carbon filament). The patient, on a sliding couch, is passed into the tunnel and cooled during treatment by an electric fan.

Lamps other than Carbon Arcs.

In the treatment of surgical tuberculosis by artificial light I would, at present, regard the Finsen side of the light department as of the greater importance, the other as accessory. The value of the other forms of lamps depends to a considerable extent on the skill with which they are used as substitutes for or combined with the various carbon arcs. To these I must briefly allude.

First, I would refer to what we call the "tunnel," which emits no ultra-violet light. (Fig. 9.) It consists merely of numerous filament lamps, carbon or tungsten, gas-filled or vacuum. It is simply radiant luminous heat. The patient, strapped on a stand, is pushed into the tunnel, and there exposed to the light of as many or as few lamps as desired. The heating effect is considerable, but the patient's skin is cooled by an electric fan which can be made to draw the air over him at varying speed. Meanwhile the long-waved light rays, having considerable penetrating effect, warm and activate the blood. The tunnel often provides a useful treatment immediately precedent to that from a short-waved lamp, such as the mercury vapour. Its greatest sphere of usefulness, however, is not in the treatment of surgical tuberculosis, but in certain other conditions.

FIG. 10.

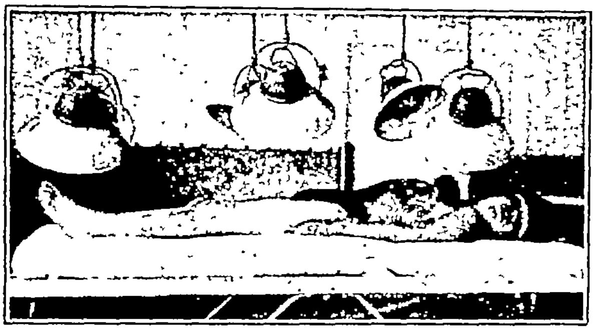


Treatment by mercury vapour lamp. Lamp in foreground has carbon filament lamps around to warm patient and activate the effect of the ultra-violet rays.

The air-cooled mercury vapour (Fig. 10) and tungsten arc lamps are so well known and so commonly used that the briefest reference will suffice. For general treatment in surgical tuberculosis they are not so valuable in my hands as the carbon arc. Rapid in their effects at first, their value appears to diminish after a few treatments. They may usefully prepare the way for, or sometimes be suitably used alternatively with, the carbon arc. In surgical tuberculosis they are more valuable for local lesions, sinuses, ulcerated lupus, suppurating or discharging glands, scrofuloderma, and the like. The water-cooled iron arc has a distinct value. It may be used with benefit in local superficial lesions. Its chief merit lies in its cheapness.

Long-waved infra-red rays are of doubtful value. (Fig. 11.) I believe they may be usefully employed for local lesions—e.g., tuberculous hips and knees in patients with low hæmobactericidal power where that is raised considerably temporarily by the use of general ultra-violet light baths. In such cases, while the bactericidal power of the blood is high, they will congest the part and I think in this way hasten the cure. For preliminary local treatment of lupus in regions other than the face, I use on the 110-volt circuit a water-cooled m.-v. lamp of the Kr. type, the value of which has been extended by the introduction of rod-like quartz applicators. The use of these applicators facilitates the treatment of mucous surfaces.

FIG. 11.



Electric radiators for infra-red rays.

I cannot now discuss the indications or contra-indications for artificial light in surgical tuberculosis, or the results achieved, and must omit many other matters associated with a light department.

One class of patient, however, should be mentioned—the patient who, though needing light treatment, is too ill to be brought to the light department or who would lose more by the movement than gain. For that patient the light department must come to him. By the kind coöperation of a well-known firm I am now engaged in perfecting a lamp specially designed for the needs of such a patient. Such a lamp must have certain essentials. It must be readily portable and simple in application, the ampèrage must be small as it will have to be plugged into an ordinary wall-plug, the light therefore must be concentrated on and yet extend the length of the patient. It must be so designed that the light generated can be used effectively and to the greatest advantage. Although certain mechanical difficulties remain yet to be overcome, I hope they will be very speedily surmounted.

It would be invidious to compare the relative merits of different makers' lamps. There are many admirable lamps on the English market to-day which may be safely recommended for special purposes with confidence. The long-flamed arc which has been advocated by and named after my friend Dr. Eidenow, is one in point. It is an excellent lamp, rich in ultra-violet light, and is rightly popular. An excellent arc lamp provided with four pairs of impregnated carbons is now on the market. It is an admirable lamp, economical in first cost and upkeep, and simple to use. It is rich in ultra-violet light, but should be used with discrimination. Indeed, I confess I have misgivings as to the use of powerful sources of ultra-violet light in the hands of the inexperienced.

Work Done in the Light Department.

During the 12 months from March 31st, 1924, to April 1st, 1925, but excluding the month of August, 1924, during which month the department was closed, the following treatments were given to patients suffering from various forms of non-pulmonary tuberculosis. Patients treated for other conditions are not here recorded.

General Carbon Arc Light Baths.

Boys	88	3787 treatments.

Total Light Treatments.

Boys	142	5542 treatments.
Girls	134	4144 „
Patients	276	9686 „

Conclusion.

As I have confined myself to the title of this communication, I fully realise how incomplete my remarks must appear. It would be desirable to compare the relative merits of sunlight and light produced by artificial means, the indications for their combined or separate use, the advantage of simultaneously or subsequently employing other physiotherapeutic aids, notably aerotherapy, balneotherapy, diathermy, and the like, but that is beyond the scope of this paper. Nevertheless, such matters must be considered carefully in prescribing light treatment; especially should the indications for artificial light and sunlight be borne in mind. I have not the very slightest hesitation in stating emphatically that certain cases derive greater benefit from the one than the other, and others are only given the maximum help by the application of both, often supplemented by other physical aids to cure. Neither have I discussed artificial light therapy in other conditions than tubercle. But this I do say, the light department has been a valuable means of assisting me in the treatment of surgical tuberculosis, and without it much that is now being accomplished at Alton could not be done at all, while much more is very definitely aided.

WAGNER-JAUREGG TREATMENT OF DEMENTIA PARALYTICA.

BY S. GROSSMAN, M.R.C.S. ENG.

(*From the Therapeutic Department, Cardiff City Mental Hospital.*)

MUCH attention has been recently given to the Wagner-Jauregg treatment of dementia paralytica by the infection of the case with malaria. Very favourable reports have been published in this country and abroad, and we decided to give it a trial at this hospital. Although only eight patients were inoculated, the difficulties encountered and the results obtained are worth recording.

One of the difficulties was to obtain permission from responsible relatives to inoculate the patients with malaria. Unfortunately, the general public does not yet appreciate the meaning of "general paralysis of the insane," and although we have about 30 general paralytics at the hospital, permission was only obtained to inoculate eight of them.

Another great difficulty was to obtain quinine-free benign tertian malarial blood. No such blood was available for a time in Cardiff, and the organism does not often survive when the blood is sent from one part to another. The opinion of Dr. C. M. Wenyon is that there is no possibility of the parasite surviving unless the blood is inoculated directly into Bass's culture medium, and the tube enclosed in a thermos flask, and so kept warm on the journey. The parasite must also have a certain amount of dextrose, otherwise it dies immediately.

Through the kindness of Dr. John Hartigan, of the Royal Hamadryad Seamen's Hospital, Cardiff, we were enabled to obtain blood from a quinine-free patient suffering from benign tertian malaria. As recommended by Dattner and Kauders, the blood was collected in 0·5 per cent. sodium citrate in physiological salt solution, the dilution being 2 parts of blood to 1 part of the solution. The blood thus obtained was examined by Dr. W. Parry Morgan, city and county bacteriologist, and the parasites in it found to belong to the species *Hæmamœba vivax* (*Plasmodium vivax*).

One patient was immediately inoculated with the diluted malarial blood, the others being inoculated with blood obtained by venous puncture from a paralytic patient suffering from benign malaria.

Technique.

The technique is quite simple. Two c.cm. of blood were injected under the skin between the scapulæ, and a simple sterile dressing applied. The patient was allowed up, but the temperature was carefully recorded twice daily. The earliest case had an incubation period of eight days; the latest, and perchance the first case inoculated, had an incubation period of 21 days. A microscopic examination of the blood was made whenever a patient developed malaria to corroborate the diagnosis. When the first attack of malaria developed the patient was put to bed at once and isolated. The greatest care was taken to keep the ward free from mosquitoes. The quinine tolerance of the patients was previously ascertained, and in one case the patient refused to take quinine on account of its bitter taste. Euquinine (quinine ethylcarbonate) in 5-grain doses twice daily was substituted for quinine sulphate on account of its freedom from taste. The powder was given in milk.

In the other cases, where the malaria ran an uninterrupted course, we followed the advice of Prof. Pilcz, and after ten attacks checked it; during the first three days by 0·5 g. of quinine twice daily, and then once daily for two weeks. At the same time, a course of neosalvarsan was given intravenously once a week, commencing with 0·3 g. and working up to 0·6 g. One case developed marked jaundice, and another hyperpyrexia with exhaustion. The splenic enlargement was easily reduced by the quinine treatment. There were no deaths amongst the inoculated patients. During the attacks hallucinations and persecutory ideas were manifest in some cases.

Case Records.

The following is a brief description of each case:—

CASE 1.—Duration of disease about 12 months.

Before inoculation patient was exalted and deluded; had very frequent hysterical attacks, during which he became very restless and noisy; it took several nurses to keep him in bed; speech slurred; memory impaired; fibrillar tremor of the tongue; pupils equal, reacted very sluggishly to light. W.R. strongly positive in blood and cerebro-spinal fluid.

Incubation period, 21 days; number of rigors, 10.

Present Condition.—Patient tolerated treatment well, but refused to take quinine. Euquinine had to be given. Physical improvement marked; mental improvement slight. No hysterical attacks since treatment.

CASE 2.—Duration of disease about 12 months.

Before treatment patient very depressed, deluded, and took no interest in his surroundings; occasionally refused food; speech slightly slurred; memory fair; fibrillar tremor of tongue; pupils unequal and fixed. W.R. negative in serum; strongly positive in cerebro-spinal fluid..

Incubation period, 8 days; number of rigors, 10.

During treatment patient was very deluded and hallucinated; after the eighth rigor he became markedly jaundiced, and this lasted until the commencement of quinine treatment.

After treatment patient gradually improved in health and mind; was able to be employed on the gardens until his discharge from the hospital; at the time of discharge he was in good health and quite rational.

CASE 3.—Duration of disease, two years (malaria before admission; Panama before the war, Mesopotamia 1917).

Patient was admitted in June, 1922. He was very confused, entirely disorientated, deluded. Pupils reacted to light; speech not slurred; W.R. negative in blood, positive in cerebro-spinal fluid; cells, 17 per c.mm. Patient's mental condition gradually improved, and he was discharged on Nov. 20th, 1922.

Readmitted on May 20th, 1923: Very boisterous and grandiose, restless and exalted; memory poor; fibrillar tremor of tongue; speech slurred; pupils reacted to light. W.R. strongly positive in blood and cerebro-spinal fluid.

Incubation Period.—Patient did not react to two inoculations at 20 days' interval.

Present State.—Patient is in fairly good health, and in a slight remission.

CASE 4.—Duration of disease, four years.

Before inoculation patient was very exalted and deluded on admission; had ideas of grandeur; memory impaired; pupils reacted sluggishly to light; gait unsteady; speech slurred. W.R. positive in blood and cerebro-spinal fluid.

At the time of inoculation patient was in fairly good physical health, and in a mild remission.

Incubation period, 10 days; number of rigors, 10.

Present State.—Patient tolerated treatment well; was very deluded during treatment; remains deluded and demented; general health improved.

CASE 5.—Duration of disease, five years.

Before Inoculation.—Patient demented and deluded; speech slurred; memory poor; pupils fixed; fibrillar tremor of tongue; health fair. W.R. strongly positive in blood and cerebro-spinal fluid.

Incubation period, 12 days; number of rigors, 1.

Remarks.—Patient became extremely ill during first attack of malaria; temp., 107° F.; very restless, with signs of exhaustion; tepid sponging failed to reduce temperature; an intramuscular injection of 1 gr. of quinine acid hydrobromide was given, and repeated in three hours; temp. gradually became normal, but physical condition of patient did not allow continuance of malaria treatment.

Present State.—Patient's mental condition became worse for a time, but gradually improved; at present patient is demented; his physical condition is fair.

CASE 6.—Duration of disease, two years.

Before Inoculation.—Patient wildly excited and exalted; incoherent; speech slurred; pupils react sluggishly to light; tongue tremulous; gait unsteady; health indifferent. W.R. strongly positive in cerebro-spinal fluid.

Incubation period, 12 days; number of rigors, 10 (not very marked).

Present State.—Patient tolerated treatment well; physical condition improved; gait much more steady; no change in mental condition.

CASE 7.—Duration of disease, 15 months.

Before Inoculation.—Patient deluded and hallucinated; speech tremulous and slurred; memory poor; gait very unsteady; hypertonicity of the whole nervous system; blindness of left eye; right eye fixed; feeble physically. W.R. strongly positive in blood and cerebro-spinal fluid.

Incubation period, 13 days; number of rigors, 10.

During treatment patient was very deluded and hallucinated; ideas of persecution marked.

Present Condition.—Patient tolerated treatment well; gradually improved physically and mentally; at present usefully employed; mental condition good; still under observation at the hospital.

CASE 8.—Duration of disease, 15 months.

Before Inoculation.—Patient was in mild remission five months; speech not slurred; gait steady; health fair; employed in the ward; pupils reacted to light and accommodation. W.R. strongly positive in blood and cerebro-spinal fluid. Since May, 1923, when patient had a series of seizures, he became very confused; speech was slurred; gait unsteady; restless by day and night; frequent seizures; health fair.

Incubation period, 8 days.

Present Condition.—Patient had no rigors; blood did not show malaria parasites; for 12 days temp. raised to 101° F.; tolerated quinine; temp. became normal, but patient became very anæmic; mental condition became worse; bedridden.

General Results (One and a Half Years after Treatment).

Of the eight cases inoculated: (*a*) Two are in a state of complete remission; one has been discharged from the hospital; the other, who is still under observation, has regained his full power to work, and is quite rational. (*b*) In two cases the improvement in the physical condition of patients is marked, and in one there is a slight mental improvement. (*c*) Two cases have not reacted well to the malarial treatment, and their mental and physical conditions remain stationary. (*d*) In one case it was found necessary to terminate the treatment during the first rigor, as the patient was becoming exhausted. (*e*) In one case repeated inoculations with malaria were unsuccessful.

Conclusions.

1. The treatment of general paralysis with benign tertian malaria is justified; the technique is simple; the fever can be easily and quickly controlled by quinine. No malaria relapses have occurred.
2. The more recent the case, the better the prognosis; but even late cases improved physically.
3. The remissions are more marked than in untreated cases.
4. An attack of malaria appears to produce immunity to artificial inoculation.
5. Arsenical medication used in any chemical combination only has failed in the treatment of general paralysis of the insane.
6. The Wassermann reaction in the blood and cerebro-spinal fluid, the Ross Jones and Weichbrodt reactions in the latter, remained unchanged. Neither are the cell-contents of the cerebro-spinal fluid influenced by the production of malaria.
7. Even in cases of complete remission some physical signs of general paralysis of the insane remain—e.g., Argyll Robertson pupil; greasy complexion; exaggerated reflexes.

I beg to thank Dr. E. Goodall, medical superintendent, for permission to publish this article.

MILK-BORNE EPIDEMICS.

BY F. W. C. BROWN, M.D., D.P.H. ABERD.,
MEDICAL OFFICER OF HEALTH, BOROUGH OF HEYWOOD.

MILK-BORNE epidemics of infectious disease, although, fortunately, not very frequent, are events which the existing laws of public health have not been adequate to abolish from our records. The possibility of any of the commoner infectious diseases being spread in a locality through such an essential food as milk, which in great part is taken into the alimentary system in the uncooked state, will always be a source of danger under existing powers. There can be little doubt that milk is the one medium from which we must expect most danger as an infection-carrying agency, being as it is of all food substances the best fitted for the multiplication of pathogenic and non-pathogenic organisms.

The main questions which arise when any milk-producing source is suspected of being responsible for widespread sudden outbursts of infectious diseases are: first, how to determine by absolute proof that the milk is the source of infection, and, secondly, how the public health official is to act in order to put an end to that source. The question of absolute proof largely depends upon the bacteriologist in the case of those diseases for which a specific organism has been found associated—e.g., typhoid fever. Unfortunately, however, in the case of scarlet fever and some others, we cannot look for any assistance from a bacteriological report. We must gather what evidence is available from such factors as the suddenness or otherwise of the epidemic, and other active causes which are common knowledge and usually quoted by text-books on the subject.

Regarding the greater of the two questions, how is the official to act? The difficulties can be fully appreciated only by investigating an actual case, such as a newly-appointed official experiences when scarlet fever is the disease to be dealt with in a district where the Infectious Disease Prevention Act of 1890 has not been adopted by the local authority concerned. Let us assume, however, that action under this adoptive Act can be taken in the majority of cases. The question of prompt action must be fully appreciated in order to deal not only with an epidemic which is proved to be milk-borne, but with one which is only suspected of being so.

The medical officer probably has his suspicions aroused by the receipt of numerous notifications of a particular disease from the medical practitioners in his district, which on further inquiry show a common milk-supply; possibly one case is located at the farm supplying that milk. Steps may be, or certainly should be, taken to remove the case at the farm forthwith, but the transmission to the milk of the infection also requires serious and prompt consideration to be of any avail. The existing powers held under Section 4 of the I.D.P.A., 1890, give powers to prohibit sale of that milk, but any possible action can only be comparatively slow in comparison with the rapid dissemination of an infective organism. Furthermore, in dealing with a case in which no help towards proof of the milk being infected can be obtained by bacteriology (as with scarlet fever), the action of preventing the sale of the milk may lead to the question of proof in a court of law, should the milk vendor consider it worth his while to so proceed.

It would appear to be time to revise the powers of dealing more promptly and more adequately with this problem.

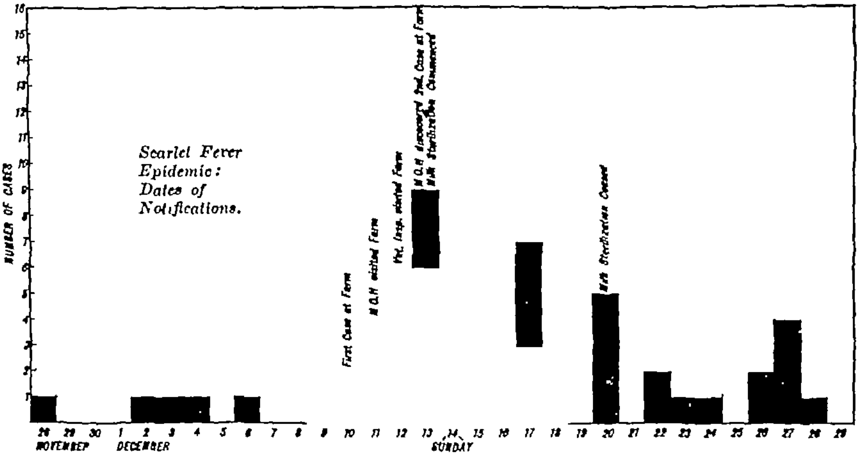
The Scarlet Fever Epidemic in Heywood in 1924.

The occurrence of an epidemic of scarlet fever in the borough of Heywood, Lancs, in December, 1924, revealed the necessity for prompt and hitherto untried methods of action. The facts which led up to the action taken by the writer may be quoted in the first instance.

Scarlet fever had not been in evidence to any abnormal extent until Dec. 10th, when the occurrence of a case at a farm supplying 180 quarts of milk daily was reported. During the following seven days 49 cases of scarlet fever were notified, the great majority of which had been receiving milk from that farm. The writer located the source of the infection at the farm, and, on visiting there, diagnosed a further case in the farmer's household. Both cases were forthwith removed to hospital and the usual disinfection carried out. Observations at the farm led to the belief that the case had ample chance of coming in contact with the milk stored in the dairy, which was not detached from the main building. The occupants of the household passed through the dairy in order to enter and leave the house. The case discovered was that of a child who was, in fact, seen to be playing with toys in and about the milk store.

Prompt action was deemed essential. To take steps under Section 4 of the I.D.P.A., 1890, would have entailed some days' delay, and one was met with the farmer's request that the milk be analysed.

It had been the writer's endeavour during 1920 to carry out laboratory experiments on a large scale on the exposure of certain pathogenic organisms in milk to varying temperatures, in order to further the knowledge necessary for rendering milk free from infection by pasteurisation methods. The results obtained were recorded in THE LANCET of August 18th, 1923, the most important conclusion arrived at being that *B. tuberculosis* in milk was rendered harmless to guinea-pigs when the infected milk had been exposed to a temperature of 60° C. for 20 minutes. During these experiments the thermal death-points of numerous other pathogenic organisms were noted, and in no case did any one of these survive this exposure to 60° C. Laboratory experiments, to be firmly established, require confirmatory tests to be carried out in practice in order fully to prove their value to the general public health. The above-mentioned epidemic therefore would appear to be a case for obtaining further proof of the actual value of pasteurisation methods; and although scarlet fever is not one of the diseases to which we can assign a specific micro-organism, yet the writer assumed that the causal organism would not be more resistant to heat than *B. tuberculosis*.



Steps were thereupon taken to carry out pasteurisation of all the milk produced at the farm in question without delay. On my suggesting to the farmer that an attempt might be made to "sterilise" the milk in order not to have his livelihood damaged for a week or two at least by prohibiting its sale, it was agreed to treat the milk by using what apparatus was available for this purpose at the farm. The apparatus consisted of an iron household wash-boiler with furnace below, several five-gallon milk-pails, and an all-glass thermometer.

The method adopted was that, with the boiler containing water kept at boiling point by the furnace, each pail was immersed in the extemporised water-bath and kept there until the temperature of the milk reached 65° C. The period required for the milk to reach this temperature was approximately 20 minutes. The pail was thereupon removed from the water-bath to make way for the next, and was then allowed to remain for 20 minutes in a warm situation. (It was found that by raising the temperature of the milk to 65° C. while in the water-bath, at the end of 20 minutes after removal the temperature had not fallen below the required 60° C.) The pail was then immersed in a trough of running cold water to reduce the temperature as much as possible before being transferred to the milk store ready for sale. In this way a continuous succession of pails were treated, and provided the furnace was fed, no hitch in the operations could occur.

The treatment of the milk was commenced on the day on which the second case of fever at the farm was diagnosed, and was carried out under supervision of the public health staff for the following seven days. By reference to the graph it will be seen that, by allowing an average of three days' incubation period following the first day of this improvised method of pasteurisation, a rapid diminution in the number of cases occurred. That a sudden fall to zero is not recorded does not disprove the beneficial effect of the pasteurisation. Many of the cases occurring from then onwards were traced to contact with the earliest cases, and consequently arose not directly (although probably indirectly) from the period during which the milk was the infective agent.

Suggestions for Similar Cases.

The experience gained by this epidemic would therefore, in the writer's opinion, seem to point to the usefulness of pasteurisation in dealing with a case in which action more stringent but perhaps more difficult to administer is contemplated.

To consider the better of the two feasible courses of action—e.g., (*a*) Section 4 of the I.D.P.A., 1890, and (*b*) pasteurisation—one must view the problem from a wide standpoint Any action under (*a*) entails delay through the red tape required by the wording of Section 4; and delay in preventing perhaps 600–1000 persons from consuming even one day's supply of infected milk is a serious consideration. Furthermore, when these powers become operative, the withholding of milk to such a large section of the community without due warning and preparation for their needs is an item requiring thought, especially where infants are concerned. On the other hand, by pasteurisation methods no delay need occur, no inconvenience to the community is entailed, and no hardships are imposed upon the conscientious farmer who may not be altogether to blame for having his milk-supply contaminated through channels difficult to discover. The question of apparatus need not be given much thought, as it is rare not to find in any farmhouse a wash-boiler the dimensions of which are sufficient to allow the immersion of the usual five-gallon pails used in dairy farms.

Clinical and Laboratory Notes.

STRANGULATED OBTURATOR HERNIA; LAPAROTOMY; RECOVERY.

BY WILSON TYSON, M.D.CAMB., F.R.C.S. EDIN.,
SURGEON, LOWESTOFT AND NORTH SUFFOLK HOSPITAL.

THE rarity of this condition is sufficient excuse for recording a case which I saw recently in consultation with Dr. W. Hotson Palmer, to whom I am indebted for the clinical history.

Mrs. S., 49, a pale, thin woman, whose health had been indifferent for several months, and who had become noticeably thinner, was seen on August 14th, two days after a journey, because of vomiting and slight abdominal pain. She stated that lately she suffered from bilious attacks once or twice a month and was constipated. No abdominal distension and no rigidity; slight general tenderness. On August 20th condition appeared to have improved, and she sat up for several hours. On August 22nd condition obviously worse; facial expression distressed. Severe abdominal pain. No action of bowels after enema, though flatus was passed. Vomiting at intervals. Seen in consultation at 5 P.M. Temperature, 100° F.; pulse, 120. Abdomen considerably distended and tender on palpation. Well-marked ladder-pattern peristalsis. No swelling in femoral or inguinal regions. Rectal and vaginal examination negative. A diagnosis of intestinal obstruction was made, and an operation was performed the same evening, Dr. Palmer kindly acting as anæsthetist.

Operation.—A right paramedian incision beginning just above the level of the umbilicus. On opening the peritoneal cavity some clear fluid escaped. The cæcum was not distended, the ordinary hernial sites were explored without result, but a distended coil of small intestine was found fixed, and on being traced down was felt to be attached to the anterior wall of the pelvis. The abdominal incision was lengthened in a downward direction and a good view obtained, when it was found that a coil of small intestine was strangulated in the obturator foramen on the right side; beyond this point the intestine was collapsed. The rest of the bowel was carefully packed off and a gentle but unsuccessful attempt was made to withdraw the strangulated bowel from the foramen. A herniotomy knife was then introduced, and the membrane notched in a downward direction. Further enlargement was obtained by working the tip of the little finger into the aperture and stretching it. Gentle traction on the bowel resulted in reduction of the hernia. There was a well-marked ring of constriction round the bowel at the site of strangulation, but it appeared viable, and on milking the contents from the distended to the collapsed bowel its colour improved. The hernial aperture was closed with two 30-day catgut mattress sutures, the abdomen closed, and the patient put back to bed with the pelvis slightly raised so as to diminish the possibility of anything adhering to the recently sutured area.

Convalescence was uneventful. The duration of the illness previous to operation was ten days; the actual strangulation can only have been of short duration, as evidenced by the viable condition of the bowel.

Ætiology and Pathology.

Obturator hernia is most frequently met with in women who have been losing fat. Out of 63 cases collected by Macready,[1] 59 were in women, whilst of 73 cases collected by Pimbet,[2] 65 occurred in women. According to Treves[1] the average age is about 60. Hutchinson[3] states that only five cases of strangulated obturator hernia occurred at the London Hospital in 20 years, whilst Rendle Short[4] reports that only one case was met with in 25 years at the Bristol Royal Infirmary.

An obturator hernia follows the obturator vessels and nerve through the upper and outer part of the obturator foramen, and pushes before it the peritoneum, subperitoneal fat, and pelvic fascia. According to Hutchinson[3] it presents three varieties: (1) It may come through above the membrane and obturator externus, being covered by the pectineus and adductor brevis; (2) it may project into the substance of the obturator externus; (3) it may pass through a gap in the muscle itself. *Relation of vessels and nerve* is not constant. Hutchinson[3] states that the vessels, as a rule, are below and to the outer side of the sac. Rendle Short[4] says cases have occurred in which the artery formed a circle round the neck of the sac. The nerve is generally to the outer side.

Contents of Sac.—The hernia may be preceded by a lipoma, as in a femoral hernia. The sac is usually small, and you may get a Richter's hernia of the small intestine (here the signs of obstruction may not be complete, flatus and even fæces passing). Occasionally by steady enlargement and stretching the sac may contain viscera of considerable size—e.g., the uterus and appendages—a protrusion from the bladder or the vermiform appendix may be present. It may occur in conjunction with a femoral hernia on the same side or it may be bilateral.

Signs, Symptoms, and Diagnosis.

A globular swelling, which may give an impulse on coughing, may be present under the pectineus; it is less mobile than a femoral hernia, has no palpable neck, and occupies a position rather more internal. The thigh may be flexed in order to relax the pectineus, whilst attempts to produce extension cause severe pain; adduction is resisted, as this movement tends to squeeze the hernia against the obturator externus.[5] Symptoms of pressure on obturator nerve: (*a*) Shooting or fixed pain referred to the inner side of the knee, perhaps even towards the foot; (*b*) flexion of hip; (*c*) weakness or spasm of adductors; (*d*) impaired sensation in terminal cutaneous branches of the nerve.

H. W. Marshall[6] records a case of associated pain in the knee and penis.

Vaginal examination allows of palpation of the pelvic aspect of the obturator foramen and may assist in diagnosis. Unless there is a visible swelling in the upper and inner part of the thigh, the condition is rarely diagnosed before death or operation for intestinal obstruction.

Prognosis.

The mortality is high. Treves[1] says that when strangulation occurs the death-rate is nearly 90 per cent. Hutchinson[7] says that of the five cases operated on at the London Hospital, there was one recovery. Firth, quoted by Hutchinson, states that five cases were saved out of 25, whilst Auerbach gives 11 recoveries out of 25 cases. Probably with modern operative methods and less reluctance to submit to operation the percentage of recoveries will be greatly increased.

Treatment.

There are three methods of approach: (1) Abdominal, (2) femoral, (3) combined abdominal and femoral. Opinion has come round in favour of the abdominal route, and in the performance of this operation the following points may be noted. A powerful illumination and the Trendelenburg position are of great assistance. It is easy to close the canal by a purse-string or by mattress sutures, as the peritoneum is loose at this site. For this reason, as Rendle Short[4] points out, another sac may form; to avoid this, he resected a piece of rib cartilage and inserted it into the canal, drawing the peritoneum over it by a purse-string suture. A lateral incision with the herniotomy knife should be avoided on account of the vessels. If the hernial sac contained firmly adherent intestine or omentum, it might be necessary to combine laparotomy with exploration from the thigh. The risk of recurrence after operation has already been mentioned, and Van Zwalenburg[8] records a case of fatal recurrence six years after operation for radical cure.

A CASE OF THROMBO-ANGIITIS OBLITERANS OF TWENTY-TWO YEARS' DURATION.*

BY F. PARKES WEBER, M.D. CAMB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO THE GERMAN HOSPITAL, LONDON.

THE patient to whom this note refers was shown by me at the Clinical Section of the Royal Society of Medicine on Dec. 13th, 1907,[1] and was described in detail in THE LANCET for Jan. 18th, 1908, under the heading Arteritis Obliterans of the Lower Extremity, with Intermittent Claudication ("Angina Cruris").[2] It was not till later in 1908 that Leo Buerger of New York[3] introduced the term "thrombo-angiitis obliterans"—the term that is now generally used for this kind of arterial disease.

M. M., a Russian Jew, aged 60 years, who came to England at the age of 25, was seen by me first in May, 1906. The symptoms had commenced gradually in 1902 or 1903 at the age of 38, with pain in the left foot on walking, of the nature of intermittent claudication. The disease progressed by exacerbations from time to time, but there were prolonged periods of quiescence, with remission or absence of pain. In 1916[4] both lower extremities showed typical erythromelalgia-like symptoms, as well as intermittent claudication and absence of pulsation in the dorsalis pedis arteries. No amputation had been performed, although the patient had passed through periods of very painful ischæmic ulceration, when gangrene seemed imminent. During one of these periods the pain, especially at night, which had commenced with slight ischæmic ulceration in one foot, lasted so long, in spite of treatment and rest in bed, that my house physician could not understand why the patient did not demand amputation as the only possible remedy. The case had been furthermore complicated from time to time (1909, 1910, 1914, 1915, 1916) with multiple foci of superficial (sometimes "nodular") phlebitis, such as has been often observed in other cases, notably in many of those described by Leo Buerger.[5]

In 1915 the patient developed a tender localised swelling in the position of the radial artery at the right wrist. Subsidence of this swelling was accompanied by apparent obliteration of the arterial channel, as evidenced by loss of pulsation. The swelling in question was seemingly due to thrombo-arteritis, and clinically analogous to the swellings which occur in nodular thrombo-phlebitis of superficial veins.

Of late the thrombo-angiitis in this case has been non-progressive, but in May, 1924, the patient was temporarily in hospital for what I regarded as a mild attack of gout at the base of both big toes. I found then to my astonishment that there was again fairly good pulsation in the left radial artery at the wrist.[6] With small doses of sodium salicylate and sodium bicarbonate the gout soon subsided, but there were also signs of chronic interstitial nephritis with high blood pressure. The urine contained a little albumin and a few granular tube-casts. The brachial systolic blood pressure was on the left (apparently sound) side 192 mm. Hg; and on the right side it was 185 mm. Hg. The painful intermittent claudication had compelled the patient to follow a sedentary mode of life which was doubtless associated with relative excess of food, and this combination had probably favoured the onset of gout and chronic interstitial nephritis. When I saw him again in March, 1925, he complained of vertigo. The urine contained a little albumin and a few hyaline and granular tube-casts. The brachial systolic blood pressure on the left side was 210 mm. Hg. It should be stated that the blood pressure in each arm had formerly (1907) been 185 mm. Hg. He still has typical intermittent claudication of both lower extremities. There is a curious network of dilated superficial venules on the back of both feet.

Family History.—The family history in the present case is remarkable. A son, aged 20, and a daughter, aged 18, both died in 1920 with diabetes mellitus. Another son formerly suffered from bronchitis and asthma. Another son, S. M., now aged 32, has been known to me since July, 1911. He formerly had a slightly enlarged spleen and used to suffer from recurrent attacks of headache and vomiting. A daughter (N. M.), of that son (S. M.), when she was 12 months old (1922), suffered from typical recurrent attacks of Raynaud's syndrome.[7] Her Wassermann reaction and the Wassermann of her father (S. M.) were negative.

The Wassermann of the present patient (the grandfather, M. M.) was examined on various occasions and was always found to be negative. Sugar was never found in his urine. There has been no evidence of saturnism. He used to be a rather free smoker of cigarettes, like nearly all patients affected with thrombo-arteritis obliterans, a disease which in London as well as in New York is found to be almost exclusively confined to Hebrews of the male sex, who themselves or whose parents have immigrated from Central Europe. Only four out of 500 cases collected by *Leo Buerger did not belong to the Semitic race.*[8]

I would add that at the German Hospital during the last two years a leg has been amputated in two bad cases (both Hebrew men) of thrombo-angiitis obliterans. In one of these cases, M. G. L., aged 48,[9] microscopic examination of the anterior tibial artery and the surrounding tissue in the amputated lower portion of the (left) leg showed a very remarkable perivascular and perineural inflammatory cell-infiltration. For this finding I am indebted to Sir Frederick Andrewes, who very kindly sent me a report of the microscopic examination. He agreed with me that this cell-infiltration might perhaps represent an ascending perivascular lymphatic inflammation, which had travelled up from a septic inflammatory focus in the foot. It certainly reminds me of the fibrotic "matting" around the vessels (due to old chronic perivascular changes),[5] described by Leo Buerger as having been found in some of his cases.[10]

9. The history of this patient had been previously recorded by Dr. Geoffrey Evans, Proc. Roy. Soc. Med., Clin. Sect., 1923, xvi., 12.
10. Leo Buerger: Op. cit., p. 320. He writes that during the stage of organisation or healing there is a development of fibrotic tissue in the adventitia, that binds together the artery, vein, and nerves.

MESSRS. J. and A. Churchill announce the early appearance of a new edition, with eight new coloured plates, of "Medical Ophthalmology," by Mr. R. Foster Moore, F.R.C.S.; a second edition of "Recent Advances in Medicine," by Dr. G. E. Beaumont and Prof. E. C. Dodds; and a new work entitled "The Diabetic Life: Its Control by Diet and Insulin," by Dr. R. D. Lawrence, chemical pathologist to King's College Hospital.

REMOVAL OF BETHLEM HOSPITAL.—The House of Lords passed the second reading of the Bethlem Hospital Bill, which provides for the removal of the hospital from its present site in the borough of Southwark to the Monks Orchard Estate at Addington in Surrey and Beckenham and West Wickham in Kent, and for the disposal of the existing buildings and convalescent home. Lord Southwark, having expressed a hope that the site might be preserved as an open space, Lord Burnham pointed out that if it was needed for public purposes a commercial price would have to be paid for it, otherwise provision for the insane would suffer. The London County Council have since decided to petition against the Bill on the ground that the utilisation of the site ought to be the subject of a scheme approved by the Minister of Health. It is urged that the land is needed for housing, recreative and educational purposes, and that the Bill in effect repeals a clause in the Bethlem Hospital Act of 1901 forbidding the letting of the site for a term of years "for building or for any other purposes."

Reviews and Notices of Books.

THE STOMACH AND UPPER ALIMENTARY CANAL IN HEALTH AND DISEASE.

By T. IZOD BENNETT, M.D. Lond., M.R.C.P., Assistant Physician to the Middlesex Hospital; Physician to the Royal National Orthopædic Hospital. London: William Heinemann. 1925. Pp. 344. 21*s*.

IN his preface the author justly alludes to the scarcity of modern books by English authors dealing with the disorders of the upper alimentary tract. And yet from his references to the literature (which includes some valuable contributions of his own) it is clear that the study of these disorders suffers no neglect in this country. The difficulty of presenting so vast a subject in a form which shall be both clear and comprehensive, and which shall embody the essentials of modern physiological and pathological teaching, has presumably acted as a deterrent to others. This difficulty the author has attempted, with no small measure of success, to overcome. He has brought to bear on the clinical problems of digestion a wealth of physiological experience, and by his familiarity with the work of his dental, radiological, and surgical colleagues, and with the needs of the student, he has avoided the imputation of producing a book of too specialist a character.

The chapters dealing with the stomach give a concise and clearly reasoned account of the present position of our knowledge of the pathology of peptic ulcer; of the disorders of gastric function dependent on organic disease; of the early diagnosis of carcinoma ventriculi; and of the scope of radiography, gastric analysis, and other laboratory investigations. Dr. Bennett is an advocate of the fractional test-meal, and his researches with the method lend authority to all his statements on gastric chemistry. A full description is given of the Sippy treatment of gastric ulcer, and while many will hold that equally good results may be obtained by less elaborate measures and that the treatment is not always well tolerated, the author claims to have employed it with satisfactory results. An account of the toxic alkalosis, which may occur in cases with commencing pyloric stenosis or renal inadequacy, should perhaps have been included. The list of indications for surgery in gastric and duodenal ulcer is most reasonable, and should give guidance to the general practitioner, whose difficulties have been increased of late by recurring disputes concerning the respective merits of surgical and medical treatment. The author asks us to hold him responsible for the opinions expressed in the book, but his general outlook is so sane and well in accord with current teaching that there is small room for disagreement. We think, however, that he somewhat over-emphasises the rarity of chronic gastritis, for is not this condition present in the majority of alcoholics, in many patients with bad pyorrhœa, and in all cases of acne rosacea? On the other hand, undue prominence is given to gastric syphilis, of which the proved cases are few.

The later chapters on diseases of the gall-bladder, liver, and pancreas contain some interesting views, especially in regard to paths of infection, and include reference to the work of Meltzer and Lyon and the indications for duodenal intubation, together with some helpful remarks on treatment. The earlier chapters, with the important exception of dental sepsis, add little to the accounts of the diseases of the mouth, pharynx, and œsophagus to be found in many of the modern text-books of general medicine.

If there is one major criticism of the book it is in relation to the poverty of its clinical description. Although the author is careful to insist on the importance of the interrogative and clinical overhaul, subjective symptoms—upon the interpretation of which all diagnosis of alimentary disease must in the first instance be based—receive too scant a reference. While it is essential that the student and practitioner should have an understanding of laboratory method and that they should appreciate its uses and limitations, it is equally essential that they should become more rather than less familiar with the early subjective and objective evidence of disease as seen at the bedside or in the consulting-room. A clearer statement of the indications for a "complete investigation," after the manner of the "indications for surgery," would enhance the utility of the book. The literary presentation and general arrangement of the volume is excellent; the illustrations (with the exception of the rather indistinct radiogram facing p. 181) and the diagrams are good; and there is a useful bibliography at the end of each chapter.

The book has no English competitor at the present time, and well-earned success may be anticipated for the volume, which will require subsequent issues to keep pace with our developing knowledge.

Diagnostik und Therapie der Magenkrankheiten.

Eighth and ninth editions. By Prof. Dr. I. BOAS, Berlin. Leipzig: G. Thieme. 1925. Pp. 817. R.M.42.

THE practitioner who has little German will probably hesitate before attempting to ingest the contents of this apparently verbose and weighty tome; but if he persists he will be amply rewarded for his effort. This text-book has long been a standard German work on diseases of the stomach, and it has been considerably enlarged and to some extent rearranged. The first half is devoted to general examination and methods of treatment; under the latter the author recommends the dry expression of the stomach contents in certain cases. In the second half some 450 pages are devoted to special diseases of the stomach. The book is well illustrated, and includes some rather intriguing coloured charts, which demonstrate the chemical contents of the more common foodstuffs and beverages; under the latter seven kinds of beer are analysed.

DIETETICS.

1. *Food and the Family.* By V. H. MOTTRAM, M.A., late Fellow of Trinity College, Cambridge; Professor of Physiology in the University of London. London: Nisbet and Co., Ltd. 1925. Pp. 240. 5*s*.

2. *Food Values.* What They Are and How to Calculate Them. Third edition. By MARGARET MCKILLOP, M.A., M.B.E., Fellow of King's College for Women, London. London: George Routledge and Sons, Ltd. 1925. Pp. 152. 3*s*. 6*d*.

3. *Diet in Health and Disease.* Sixth edition. By JULIUS FRIEDENWALD, M.D., Professor of Gastro-Enterology, and JOHN RUHRAH, M.D., Professor of Diseases of Children, University of Maryland School of Medicine, Baltimore. London and Philadelphia: W. B. Saunders Company. 1925. Pp. 987. 37*s*. 6*d*.

(1) Prof. Mottram writes in a pleasant style, and although his little book is definitely intended for the lay reader it will prove interesting even to the scientific dietitian. After an account of what food can do in promoting and maintaining health, there follows a chapter in which various food views are discussed from the physiological standpoint. Chapter III. deals with the nature and functions of food, and in popular language the various constituents of food are explained and discussed. This leads on to the question of food as an energy producer, and here we meet the calorie for the first time, when Prof. Mottram is at his very best. The calorie value of various foodstuffs is discussed, and even those who, like the author, as he amusingly confesses, cannot do simple arithmetic will not find this section either difficult or boring. The food budgets of the professional man and of the working man are analysed, and the originality of the book lies in the way in which the cost of food is considered in view of the calorie value obtained.

Fresh herrings head the list for the cheapest way of obtaining a daily animal protein ration for only 2¾*d.*, and a subsistence diet of over 3000 calories can be obtained from fresh herrings, oatmeal, and cabbage, which costs only 5¾*d.* a day and yet contains all the physiological requisites! This rock-bottom diet serves as a background for criticism of food in general. The egg as a cheap food is exploded completely, for it appears that eggs are dearer than any other given food for proteins and dearer than most familiar foods except cod and sole for calories, while the vitamins contained in eggs can be obtained more cheaply in other ways. This is an example of how the subject is treated by one who seems to know as much about housekeeping as he does about physiology, and this is high praise. There are a few minor points which may be criticised. "Acidity" of the blood, even when the offending word is put between inverted commas (p. 80), is not a good term, and if "rarely met with outside the walls of a hospital" is never met with inside. To say that cod-liver oil will alter "the state of a child within a few hours from dullness and disinterest in food to playfulness and a good appetite" (p. 90) is surely exaggeration, and the statement that "all children brought up on dried milk need a teaspoonful or two of orange or tomato juice per day" (p. 100) is a little dangerous and vague in view of the fact that even this quantity will fail to prevent scurvy in some cases; in a book intended for the lay public the minimum should be set higher. We commend the book to all interested in the subject, and this is a very large section of the public.

(2) To those who are reading Prof. Mottram's book, "Food Values" will prove useful for the tables it contains. Since its first appearance in 1916 the author has had much practical experience in the Ministry of Food during the war, and consequently much of the present edition has been rewritten, the most important change being the substitution of English analyses of food for American analyses. The preliminary part of the book contains an account of food requirements, a whole chapter is devoted to vitamins and another to the brown bread controversy, while the greater part consists of tables of food analyses, dietary requirements, and daily diets.

(3) "Diet in Health and Disease" is in quite a different category from the other two books here under review. It is essentially a reference book to meet the needs of the medical profession, and contains a full treatment of the whole subject of food analysis and food requirements, while the bulk of the work is taken up with an account of suitable diets for use in disease. The first edition appeared in 1904, and since then the book has been constantly revised, so that the sixth edition not only differs considerably from the first, but also from the fifth and contains many additions, while many sections have been rewritten. For example, changes in the sections on food poisoning, on diabetes, on cœliac disease, and on nephritis have been rendered necessary by the progress of medical science. The authors claim that dietetics may now be regarded as probably at least half scientific and half empirical, but a perusal of this book, with its many tables, gives the impression that this is a modest estimate. Not a few of the dishes discussed are unknown in this country.

DIATHERMY IN GONOCOCCAL INFECTION.

Treatment of Gonococcal Infection by Diathermy. By E. P. CUMBERBATCH, M.A., B.M., B.Ch. Oxf., M.R.C.P., Medical Officer in Charge of the Electrical Department of St. Bartholomew's Hospital; and C. A. ROBINSON, M.B., B.Ch., D.M.R.E. *Camb.*, Medical Officer in Charge of Electrical Department, West Middlesex Hospital. London: Wm. Heinemann, Ltd. 1925. Pp. 150. 7*s.* 6*d.*

THIS admirable monograph records the results obtained by the writers in the treatment of gonococcal infection (with or without complications) by diathermy. The treatment is described in detail and the facts are presented so moderately as to leave no doubt in the mind of the unbiased that diathermy in the hands of careful experts has a wide field of usefulness in the treatment of these conditions. The authors very wisely do not claim absolute cure as inevitable after a course of treatment by diathermy, but their cases quoted—with clinical notes before and after treatment—are in almost every case highly satisfactory.

An appendix describes five cases of arthritis where the cervix uteri seemed to be the focus of infection, but where gonococcal infection was not proved by pathological tests; these cases showed gratifying improvement after application of diathermy to the urethra and cervix, and should stimulate practitioners who have patients suffering from arthritis to have a pelvic examination made in every case where the primary focus of infection has not been satisfactorily discovered.

SURGERY OF THE EYE.

A Handbook for Students and Practitioners. Second edition. By ERVIN TÖRÖK, M.D., and GERALD H. GROUT, M.D., Surgeons to the Herman Knapp Memorial Eye Hospital, New York. London: Baillière, Tindall and Cox. 1925. With 510 illustrations. Pp. 484. 30*s.*

WE have here a sound guide to the chief operations of ophthalmic surgery. This book opens with two chapters for which house surgeons should be especially grateful: the first on surroundings and general preparation for eye operations, the second on instruments and their management. The operations described in the second part of the book are those which in the hands of the majority of experienced ophthalmologists procure the best results. Under the heading Cataract, linear extraction with a keratome and flap extraction with a Graefe knife, with or without iridectomy, are described in a way which should be really helpful, the numerous figures assisting much; the intracapsular methods—e.g., Smith's and Barraquer's—are only briefly referred to. Under Glaucoma the three main operations—the classical iridectomy and sclerectomy according to the two methods of Lagrange and Elliot—are fully described; less important operations such as the cyclodialysis of Heine are also referred to and figured.

The multiplication of methods described for lid operations in text-books is apt to be confusing to the student, especially the various operations for entropion and ectropion and for ptosis. The procedures detailed in this book are well chosen, but may need supplementing for exceptional cases. The operation for extirpation of the lacrymal sac is so important that it might have been given a rather fuller exposition, especially with regard to the normal anatomy of the lacrymal canal, and we miss any reference to the alternative (intranasal) methods of dealing with dacryocystitis.

The large number of illustrations help to make the descriptions intelligible. On the whole, this is one of the best books on the subject that has reached us.

MODERN NURSING OF CONSUMPTION.

Second edition. By Dr. JANE WALKER. London: Scientific Press, Ltd. 1924. Pp. 75. 2*s.* 6*d.*

THIS little book on the nursing of consumption is full of useful obiter dicta, common sense, and wit. There can be no doubt that sanatorium nursing taxes the patience of a nurse to the utmost; outside the sanatorium there is nothing but bucolic monotony, and inside there is a routine seldom, if ever, enlivened by that whiff of chloroform and gleam of the surgeon's knife which provide the thrills making surgical nursing so curiously popular. Dr. Walker has done a great service in describing sanatorium nursing in such a way that, though she does not invest it with an impossible halo, she introduces a certain amount of much-needed colour into the picture.

Reviews and Notices of Books.

THE STOMACH AND UPPER ALIMENTARY CANAL IN HEALTH AND DISEASE.

By T. IZOD BENNETT, M.D. Lond., M.R.C.P., Assistant Physician to the Middlesex Hospital; Physician to the Royal National Orthopædic Hospital. London: William Heinemann. 1925. Pp. 344. 21s.

IN his preface the author justly alludes to the scarcity of modern books by English authors dealing with the disorders of the upper alimentary tract. And yet from his references to the literature (which includes some valuable contributions of his own) it is clear that the study of these disorders suffers no neglect in this country. The difficulty of presenting so vast a subject in a form which shall be both clear and comprehensive, and which shall embody the essentials of modern physiological and pathological teaching, has presumably acted as a deterrent to others. This difficulty the author has attempted, with no small measure of success, to overcome. He has brought to bear on the clinical problems of digestion a wealth of physiological experience, and by his familiarity with the work of his dental, radiological, and surgical colleagues, and with the needs of the student, he has avoided the imputation of producing a book of too specialist a character.

The chapters dealing with the stomach give a concise and clearly reasoned account of the present position of our knowledge of the pathology of peptic ulcer; of the disorders of gastric function dependent on organic disease; of the early diagnosis of carcinoma ventriculi; and of the scope of radiography, gastric analysis, and other laboratory investigations. Dr. Bennett is an advocate of the fractional test-meal, and his researches with the method lend authority to all his statements on gastric chemistry. A full description is given of the Sippy treatment of gastric ulcer, and while many will hold that equally good results may be obtained by less elaborate measures and that the treatment is not always well tolerated, the author claims to have employed it with satisfactory results. An account of the toxic alkalosis, which may occur in cases with commencing pyloric stenosis or renal inadequacy, should perhaps have been included. The list of indications for surgery in gastric and duodenal ulcer is most reasonable, and should give guidance to the general practitioner, whose difficulties have been increased of late by recurring disputes concerning the respective merits of surgical and medical treatment. The author asks us to hold him responsible for the opinions expressed in the book, but his general outlook is so sane and well in accord with current teaching that there is small room for disagreement. We think, however, that he somewhat over-emphasises the rarity of chronic gastritis, for is not this condition present in the majority of alcoholics, in many patients with bad pyorrhœa, and in all cases of acne rosacea? On the other hand, undue prominence is given to gastric syphilis, of which the proved cases are few.

The later chapters on diseases of the gall-bladder, liver, and pancreas contain some interesting views, especially in regard to paths of infection, and include reference to the work of Meltzer and Lyon and the indications for duodenal intubation, together with some helpful remarks on treatment. The earlier chapters, with the important exception of dental sepsis, add little to the accounts of the diseases of the mouth, pharynx, and œsophagus to be found in many of the modern text-books of general medicine.

If there is one major criticism of the book it is in relation to the poverty of its clinical description. Although the author is careful to insist on the importance of the interrogative and clinical overhaul. subjective symptoms—upon the interpretation of which all diagnosis of alimentary disease must in the first instance be based—receive too scant a reference. While it is essential that the student and practitioner should have an understanding of laboratory method and that they should appreciate its uses and limitations, it is equally essential that they should become more rather than less familiar with the early subjective and objective evidence of disease as seen at the bedside or in the consulting-room. A clearer statement of the indications for a "complete investigation," after the manner of the "indications for surgery," would enhance the utility of the book. The literary presentation and general arrangement of the volume is excellent; the illustrations (with the exception of the rather indistinct radiogram facing p. 181) and the diagrams are good; and there is a useful bibliography at the end of each chapter.

The book has no English competitor at the present time, and well-earned success may be anticipated for the volume, which will require subsequent issues to keep pace with our developing knowledge.

Diagnostik und Therapie der Magenkrankheiten. Eighth and ninth editions. By Prof. Dr. I. BOAS, Berlin. Leipzig: G. Thieme. 1925. Pp. 817. R.M.42.

THE practitioner who has little German will probably hesitate before attempting to ingest the contents of this apparently verbose and weighty tome; but if he persists he will be amply rewarded for his effort. This text-book has long been a standard German work on diseases of the stomach, and it has been considerably enlarged and to some extent rearranged. The first half is devoted to general examination and methods of treatment; under the latter the author recommends the dry expression of the stomach contents in certain cases. In the second half some 450 pages are devoted to special diseases of the stomach. The book is well illustrated, and includes some rather intriguing coloured charts, which demonstrate the chemical contents of the more common foodstuffs and beverages; under the latter seven kinds of beer are analysed.

DIETETICS.

1. *Food and the Family.* By V. H. MOTTRAM, M.A., late Fellow of Trinity College, Cambridge; Professor of Physiology in the University of London. London: Nisbet and Co., Ltd. 1925. Pp. 240. 5s.

2. *Food Values.* What They Are and How to Calculate Them. Third edition. By MARGARET MCKILLOP, M.A., M.B.E., Fellow of King's College for Women, London. London: George Routledge and Sons, Ltd. 1925. Pp. 152. 3s. 6d.

3. *Diet in Health and Disease.* Sixth edition. By JULIUS FRIEDENWALD, M.D., Professor of Gastro-Enterology, and JOHN RUHRÄH, M.D., Professor of Diseases of Children, University of Maryland School of Medicine, Baltimore. London and Philadelphia: W. B. Saunders Company. 1925. Pp. 987. 37s. 6d.

(1) Prof. Mottram writes in a pleasant style, and although his little book is definitely intended for the lay reader it will prove interesting even to the scientific dietitian. After an account of what food can do in promoting and maintaining health, there follows a chapter in which various food views are discussed from the physiological standpoint. Chapter III. deals with the nature and functions of food, and in popular language the various constituents of food are explained and discussed. This leads on to the question of food as an energy producer, and here we meet the calorie for the first time, when Prof. Mottram is at his very best. The calorie value of various foodstuffs is discussed, and even those who, like the author, as he amusingly confesses, cannot do simple arithmetic will not find this section either difficult or boring. The food budgets of the professional man and of the working man are analysed, and the originality of the book lies in the way in which the cost of food is considered in view of the calorie value obtained.

Fresh herrings head the list for the cheapest way of obtaining a daily animal protein ration for only 2½d., and a subsistence diet of over 3000 calories can be obtained from fresh herrings, oatmeal, and cabbage, which costs only 5½d. a day and yet contains all the physiological requisites! This rock-bottom diet serves as a background for criticism of food in general. The egg as a cheap food is exploded completely, for it appears that eggs are dearer than any other given food for proteins and dearer than most familiar foods except cod and sole for calories, while the vitamins contained in eggs can be obtained more cheaply in other ways. This is an example of how the subject is treated by one who seems to know as much about housekeeping as he does about physiology, and this is high praise. There are a few minor points which may be criticised. "Acidity" of the blood, even when the offending word is put between inverted commas (p. 80), is not a good term, and if "rarely met with outside the walls of a hospital" is never met with inside. To say that cod-liver oil will alter "the state of a child within a few hours from dullness and disinterest in food to playfulness and a good appetite" (p. 99) is surely exaggeration, and the statement that "all children brought up on dried milk need a teaspoonful or two of orange or tomato juice per day" (p. 100) is a little dangerous and vague in view of the fact that even this quantity will fail to prevent scurvy in some cases; in a book intended for the lay public the minimum should be set higher. We commend the book to all interested in the subject, and this is a very large section of the public.

(2) To those who are reading Prof. Mottram's book, "Food Values" will prove useful for the tables it contains. Since its first appearance in 1916 the author has had much practical experience in the Ministry of Food during the war, and consequently much of the present edition has been rewritten, the most important change being the substitution of English analyses of food for American analyses. The preliminary part of the book contains an account of food requirements, a whole chapter is devoted to vitamins and another to the brown bread controversy, while the greater part consists of tables of food analyses, dietary requirements, and daily diets.

(3) "Diet in Health and Disease" is in quite a different category from the other two books here under review. It is essentially a reference book to meet the needs of the medical profession, and contains a full treatment of the whole subject of food analysis and food requirements, while the bulk of the work is taken up with an account of suitable diets for use in disease. The first edition appeared in 1904, and since then the book has been constantly revised, so that the sixth edition not only differs considerably from the first, but also from the fifth and contains many additions, while many sections have been rewritten. For example, changes in the sections on food poisoning, on diabetes, on coeliac disease, and on nephritis have been rendered necessary by the progress of medical science. The authors claim that dietetics may now be regarded as probably at least half scientific and half empirical, but a perusal of this book, with its many tables, gives the impression that this is a modest estimate. Not a few of the dishes discussed are unknown in this country.

DIATHERMY IN GONOCOCCAL INFECTION.

Treatment of Gonococcal Infection by Diathermy. By E. P. CUMBERBATCH, M.A., B.M., B.Ch. Oxf., M.R.C.P., Medical Officer in Charge of the Electrical Department of St. Bartholomew's Hospital; and C. A. ROBINSON, M.B., B.Ch., D.M.R.E. Camb., Medical Officer in Charge of Electrical Department, West Middlesex Hospital. London: Wm. Heinemann, Ltd. 1925. Pp. 150. *7s. 6d.*

THIS admirable monograph records the results obtained by the writers in the treatment of gonococcal infection (with or without complications) by diathermy. The treatment is described in detail and the facts are presented so moderately as to leave no doubt in the mind of the unbiased that diathermy in the hands of careful experts has a wide field of usefulness in the treatment of these conditions. The authors very wisely do not claim absolute cure as inevitable after a course of treatment by diathermy, but their cases quoted—with clinical notes before and after treatment—are in almost every case highly satisfactory.

An appendix describes five cases of arthritis where the cervix uteri seemed to be the focus of infection, but where gonococcal infection was not proved by pathological tests; these cases showed gratifying improvement after application of diathermy to the urethra and cervix, and should stimulate practitioners who have patients suffering from arthritis to have a pelvic examination made in every case where the primary focus of infection has not been satisfactorily discovered.

SURGERY OF THE EYE.

A Handbook for Students and Practitioners. Second edition. By ERVIN TÖRÖK, M.D., and GERALD H. GROUT, M.D., Surgeons to the Herman Knapp Memorial Eye Hospital, New York. London: Baillière, Tindall and Cox. 1925. *With 510 illustrations. Pp. 484. 30s.*

WE have here a sound guide to the chief operations of ophthalmic surgery. This book opens with two chapters for which house surgeons should be especially grateful: the first on surroundings and general preparation for eye operations, the second on instruments and their management. The operations described in the second part of the book are those which in the hands of the majority of experienced ophthalmologists procure the best results. Under the heading Cataract, linear extraction with a keratome and flap extraction with a Graefe knife, with or without iridectomy, are described in a way which should be really helpful, the numerous figures assisting much; the intracapsular methods—e.g., Smith's and Barraquer's—are only briefly referred to. Under Glaucoma the three main operations—the classical iridectomy and sclerectomy according to the two methods of Lagrange and Elliot—are fully described; less important operations such as the cyclodialysis of Heine are also referred to and figured.

The multiplication of methods described for lid operations in text-books is apt to be confusing to the student, especially the various operations for entropion and ectropion and for ptosis. The procedures detailed in this book are well chosen, but may need supplementing for exceptional cases. The operation for extirpation of the lacrymal sac is so important that it might have been given a rather fuller exposition, especially with regard to the normal anatomy of the lacrymal canal, and we miss any reference to the alternative (intranasal) methods of dealing with dacryocystitis.

The large number of illustrations help to make the descriptions intelligible. On the whole, this is one of the best books on the subject that has reached us.

MODERN NURSING OF CONSUMPTION.

Second edition. By Dr. JANE WALKER. London: Scientific Press, Ltd. 1924. Pp. 75. *2s. 6d.*

THIS little book on the nursing of consumption is full of useful obiter dicta, common sense, and wit. There can be no doubt that sanatorium nursing taxes the patience of a nurse to the utmost; outside the sanatorium there is nothing but bucolic monotony, and inside there is a routine seldom, if ever, enlivened by that whiff of chloroform and gleam of the surgeon's knife which provide the thrills making surgical nursing so curiously popular. Dr. Walker has done a great service in describing sanatorium nursing in such a way that, though she does not invest it with an impossible halo, she introduces a certain amount of much-needed colour into the picture.

MY MOORLAND PATIENTS.

By a Yorkshire Doctor. Edited by J. C. POWELL. London: John Murray. 1924. Pp. 242. 7*s.* 6*d.*

WE are glad to see that this book, the first edition of which was reviewed in our columns, is now issued in a cheaper edition, especially as the cheapness, so far as we can see, has not been put into the paper, the printing, or the illustrations. As a record of a state of manners and customs which are rapidly passing, or indeed have entirely disappeared, the volume is most valuable, and makes excellent reading. The "Yorkshire Doctor" was Dr. R. W. S. Bishop, who died in 1921.

EPSOM COLLEGE: THE ANNUAL MEETING.

THE annual meeting of the governors of Epsom College was held at the offices, 49, Bedford-square, London, W.C., on June 27th, when Dr. Raymond Crawfurd presided. The secretary read the names of the successful candidates as follows:—

"Christie," "Pugh," and Ordinary Pensionerships.

Addressing the governors, the Chairman said that he hoped this would be a memorable year in the annals of the College and one pregnant of far-reaching results. Increased support from the profession and others had enabled the Council to face increased commitments in various directions. In their determination to attain the highest educational level, they had made substantial improvements in the pecuniary prospects of the masters. The year had seen the completion of the rebuilding of the chapel as a memorial to the masters and boys who fell in the war. The reconstructed chapel, a brick basilica of admirable internal proportions, now embodied worthily the spiritual aspirations of the College. A new chemical block, that had been thought and talked about for so many years, was now actually in hand, and had been made possible by several generous bequests that had come to hand. The vacated space would afford much-needed additional accommodation for class-rooms and lecture-room, and for an improved natural history museum. The Council were now in the position, by the munificence of a good benefactress, to carry out a complete transformation of the existing library, and to make it far more attractive and serviceable to the boys, and Dr. Crawfurd expressed the hope that similar help from some other quarter might be forthcoming towards the equipment of a museum, worthy of a school that supplies so many recruits to scientific professions; £500 would solve all difficulties in that direction. Another need of the College, that might well appeal to those of sporting instincts, was the levelling and extension of some parts of the playing fields, so that all the boys might play their games under more inspiriting conditions. The Bursar had secured an estimate for the work, which showed that it could be well done for £1500. These things were beyond the capacity of the normal revenue of the College; which this year was bearing the cost of an extensive substitution of electric light for gas, and which would almost at once have to provide better washing and drying facilities in the Lower School, and probably in the not distant future to undertake the centralisation of a scattered and wasteful system of heating and hot-water supply.

The Chairman concluded on a note of gratitude to all who had helped them; to their good subscribers, donors, and benefactors; to their organisation of local secretaries, which he wished to extend far more widely; to the great medical institutions, and the medical press. He also asked for special thanks to Mr. Gerald Stanley who had established at his own expense a scholarship giving free education at the College, and to Mr. Arthur Chudleigh, who had given to the chapel a silver-plated cross, six candlesticks, and vases for the altar, and an alms dish. He hoped that the generosity of all these might prove contagious in many quarters.

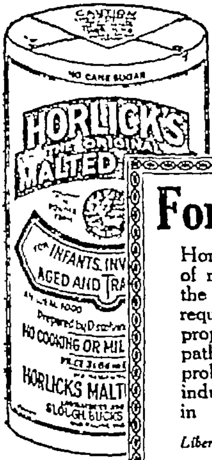
On the motion of the Chairman, the report of the income and expenditure account was adopted and the Council and officers for the year were elected or re-elected. On the motion of Dr. F. de Havilland Hall, seconded by Sir StClair Thomson, Dr. Crawfurd, who has worked so untiringly for the College and has collected over £1000 in subscriptions, was elected a Vice-President.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANÆSTHETICS: PROVINCIAL MEETING.

A PROVINCIAL meeting of this Section was held on June 27th at Manchester, Mr. H. E. G. BOYLE, President, in the chair. The members were most hospitably entertained by their northern fellows, and after luncheon in the University Refectory adjourned to the lecture room and physiological laboratories.—Dr. H. P. FAIRLIE read a paper on Chloroform Anæsthesia, in which he deprecated the view that chloroform should never be used. It was, in his view, often the best anæsthetic, but only in the hands of those who were thoroughly experienced in its use. The fatigue caused to the patient by prolonged ether inhalation could often be averted by judicious employment of chloroform.—Dr. J. BLOMFIELD pointed out the difference between the two kinds of chloroform fatality, one avoidable and the other not, and agreed that when proper selection of anæsthetics for all cases was practised chloroform would often be chosen and used by the expert.—Dr. S. R. WILSON described the causation of ventricular fibrillation, and pointed out the fallacy of preliminary atropine if chloroform fatalities were ascribed to vagus inhibition.—Dr. W. J. MCCARDIE alluded to the advantages of mixture with varying proportions of chloroform.—Mr. G. RAMSEY PHILLIPS alluded to the arrangement for increasing concentration of chloroform into the Vernon Harcourt inhaler.—Dr. KIRKBY THOMAS described the safety inherent in the low position of the patient's head.—Dr. ANDREW WILSON described deaths which had occurred before the administration of the anæsthetic had commenced and agreed with the observations of Dr. Fairlie and Dr. Blomfield.—Dr. H. W. FEATHERSTONE described the difference in resuscitating those patients who collapsed under chloroform compared with similar cases under other anæsthetics.—In the laboratory Dr. S. R. WILSON and Dr. S. MCSWINEY demonstrated the effects of intravenous injection of adrenalin into animals anæsthetised with ether and with chloroform, and a number of charts and of different kinds of apparatus was also demonstrated.



For Infant Feeding

Horlick's Malted Milk—the Original—supplies all the elements of nutrition in Cereals and Milk in proper proportions and with the amylolytic conversion of starch, thus fulfilling the physiological requirements of Infants and constituting the characteristics of a proper diet in Infancy. It is dependable in all climates, free from pathogenic organisms, and affords a solution to the pure milk problem, as well as the prevention of those diseases often induced by amylaceous foods. Complete in itself and ready in a moment by briskly stirring the powder in water only.

Liberal samples free to Members of the Profession.

MALARIA IN EUROPE.

IN 1924 the Permanent Health Committee of the League of Nations appointed a Malaria Commission composed of seven members, several experts, and a number of corresponding members to inquire into the incidence and epidemiology of malaria in Europe, and to investigate the problem of quinine administration. The results of these inquiries in Italy, Russia, and the Balkan States have recently been published,[1] and we are informed that further reports on other countries will be issued from time to time. The itinerary of the tour was a comprehensive one, and occupied a period of three months of continuous travel. Commencing in May, 1924, the Commission visited Dalmatia, Serbia, Greece, Bulgaria, Roumania, Russia (Ukraine, Don basin, Caucasus, Volga region, and Moscow), and Italy, eventually dispersing at Rome on August 28th. A large amount of data of a general nature has been accumulated, though no facts of a novel or striking nature have emerged. The greater part of the information was obtained from the health departments of the countries visited.

Special interest centres on the spread of malaria in Russia which has taken place since the war. The most malarial part of this country is undoubtedly the Middle Volga district. Before the war 400 cases of malaria for every 10,000 inhabitants were registered there yearly, and in 1923 in the German Republic of the Volga the disease became epidemic, so that approximately half the inhabitants were infected. This extraordinary spread of malaria in the Volga district, as indeed in the whole of Russia, was largely a result of the European War, aided by civil war in Russia with all its consequences. The population was forced through fear of starvation to emigrate to Turkestan, Bokhara, and the Caucasus, whence the severe forms (subtertian parasite) were imported. In the Volga district the geographical features of the river are held to be mainly responsible for the spread of the disease. It appears that the meadows on each side of the river are inundated in spring time, and on subsidence of the floods permanent pools remain which constitute the breeding grounds of mosquitoes. In this district there are, as a rule, two rises of malaria incidence during the year; the spring increase commences in March, when the anophelines are not found; the autumn epidemic, commencing about August, is undoubtedly spread by the swarms of newly-hatched mosquitoes which then abound. The spring epidemic consists, as has been noted in Salonica, Palestine, and elsewhere, almost entirely of benign tertian malaria, probably relapses of a previous infection; in August and September the subtertian parasite predominates, and has accounted for 85 per cent. of the cases. The quartan form appears to occur only at the cold season of the year. As regards Russia in general, the information indicates that the accounts of the effects of malaria, as described in some English journals, are greatly exaggerated. In that country epidemic malaria reached its maximum in 1923, when the deaths due to the disease were estimated at 60,000 (0·4 per mille of population), a figure hardly comparable with the average death-rate in badly infected districts in British India, where the disease usually causes a death-rate at least ten times that figure. The occurrence of epidemic malaria in Europe is by no means a new event. The most important factors concerned in the recent epidemic appear to have been: (1) The importation of new cases and carriers into areas where malaria was already endemic; (2) the importation and aggregation of susceptible people, particularly in connexion with the settlement of refugees and colonists in the endemic areas; (3) various social and economic circumstances, especially, in some countries, a great lack of quinine. Undoubtedly, if the countries concerned had a properly organised medical or sanitary service much could be done to eliminate nearly all these factors. As regards the endemicity of malaria in Europe, the important rôle of "house infection" in the spread and maintenance of the disease impressed itself greatly on the Commission. It is essentially a family or household affair, to be explained by the close and continuous association existing in most dwellings between the human source of infection, the insect carrier, and the human recipient to which the domestic habits of *Anopheles maculipennis* especially lend themselves.

The large amount of data collected by a commission of such a comprehensive nature makes it difficult to crystallise the main trend of the work, but the general impression may best be gathered from the wholly admirable summary by Colonel S. P. JAMES, the British representative. He points out that, with the exception of Italy, the vital statistics with reference to malaria are inadequate and are therefore not comparable with the methods usually employed in malarious tropical countries. In the absence of these necessary statistics the information as to the past and present incidence of malaria in the countries visited is vague and imperfect, but it is known that from time to time, at irregular intervals, all these countries have experienced, in addition to this endemic malaria, striking invasions of the disease in epidemic form, which has spread to localities previously free. Very little information could be obtained as to the effects of the recent epidemic wave. In Dalmatia, it is true, and in Serbian Macedonia numbers of patients were seen suffering from greatly enlarged spleen, the result, probably, of the epidemic disease, but elsewhere the epidemic had abated almost completely and the distribution of malaria has once more become restricted to its original endemic centres. Little information was likewise obtainable about the mortality which the epidemic may have caused in different countries and still less about the severity of the cases. To those with experience of malaria in tropical countries the absence of evidence of a high fatality was very surprising. The impression obtained, however, was that there is no area in Europe in which the fatality of the recent wave of malaria is even remotely comparable with the fatality of the disease as seen in the Punjab during the epidemic of 1908, when the deaths were 13 times more numerous than the normal. In Greek Macedonia the epidemic of 1923 is said to have caused 700 deaths amongst 10,000 refugees, but none of the figures given, either here or in Roumania or Bulgaria, is anything but approximately correct. In suggesting antimalarial measures due consideration has to be paid to the incompleteness of the sanitary services which has resulted from the war, and to the fact that in Europe malaria is one of the least, in contrast to the tropics, where it constitutes the most dangerous endemic disease. The Commission therefore deprecates the undertaking of costly antimalarial measures in circumstances where such action is of doubtful value and when the money would be better employed in other essential health services. Every effort should therefore be made to combat endemic malaria in Europe in the *houses* of the people themselves rather than in the environment. The competent sanitary authority should enter the houses of the people, treat those infected, and educate them to kill off the few sluggish "domesticated" anophelines whose wants are all supplied in that particular house and who constitute the chief sources of infection. In this simple way more good will be done than by the most extensive measures against larvæ and adult insects in the environment. Unfortunately, this decision involves the onus of overcoming the well-recognised difficulty that medical officers and sanitarians who have become interested in the elimination of breeding places and in engineering problems of drainage are usually loth to discard those measures. The outstanding fact is once more emphasised that it is by a well-equipped medical and public health service that malaria in Europe will be eventually eradicated. That this has been the case in England is set out forcefully by Colonel A. W. ALCOCK on another page. By applying this lesson to European countries in general the League of Nations Commission has rendered a valuable and permanent service.

PAY HOSPITALS FOR PATIENTS OF MODERATE MEANS.

SUNDAY last, June 28th, was "Hospital Sunday"; the financial results of the day have not yet been published, but it is to be hoped that a substantial sum will be returned to the coffers of the Metropolitan Hospital Sunday Fund. The hospitals are struggling against grave financial difficulties and their future is problematical unless they can be established on some sounder basis than the present one. Among other schemes proposed is the extension of their wards to paying patients. The question of institutional accommodation for the middle-class patient has become acute during recent years. Many schemes have been put forward on paper and several have been tried in practice, with a varying measure of success. The Conference of the British Hospitals Association, held in Manchester on June 25th, debated the subject once more. Sir WILLIAM MILLIGAN pointed out that the poor are admirably looked after and cared for, while the rich are quite competent to look after their own interests; but an increasingly large number of those of moderate means find it more and more difficult, owing to the expense entailed, to secure those benefits from recent advances in medicine and surgery to which they are entitled. Consequently, and more especially within recent years, large numbers of the middle classes are forced, often against their inclinations and wishes, to seek treatment in existing voluntary hospitals, with the result that waiting lists attain quite inordinate dimensions and serious economic loss to the community results from delay in admission and the prolonged abstention from work of the wage-earner. Moreover, the public have recognised that modern medicine and surgery have become more complex and more detailed, and that the numerous adventitious aids to exact diagnosis are found to exist to more advantage within the walls of some great institution rather than in the chambers of any individual physician or surgeon, however well equipped his consulting rooms may be. The tendency, therefore, to resort to institutional treatment is not unnatural, is becoming more accentuated every year, and is a tendency which is likely to go on growing, considering the undeniable advantages which it presents. The provision of a limited number of wards or beds for paying patients is already an accomplished fact in certain hospitals, and has been the means of meeting, to some slight extent, the existing demand for institutional treatment at moderate fees. At the moment it is at any rate a quite inadequate provision for existing requirements, does not always afford that privacy, which is its main objective, and proves a complicated arrangement so far as hospital accounts and hospital administration are concerned.

Sir WILLIAM MILLIGAN's proposal is that a "pay hospital" should be established in connexion with each large general hospital. Certain services, such as lighting, heating, laundering, catering, and nursing could be arranged in common for the two institutions, thus lightening the financial burden and widening the experience of the nursing staff. The fundamental regulations suggested by Sir WILLIAM MILLIGAN were:

1. That the Committee of Management should consist of three members elected by the parent hospital, three by the preference shareholders, and three prominent citizens, and should meet monthly.
2. That a resident medical officer should take charge of the patients under the direction of the specialist.
3. That no patient be admitted without a written recommendation from a duly registered medical practitioner.
4. That the income limit for admission should be £600 and the charge be 6 guineas per week; fees for special nurse, anæsthetic, X ray, or pathological report being extras.
5. That the patient be free to employ any member of the staff of any hospital, arranging the fees with him personally.
6. That the practitioner on whose recommendation the patient is admitted have free access to see his patient at any time but that he have no responsibility in the matter of treatment.
7. That if a case does not necessitate the advice of a consultant the onus of treatment shall rest with the resident medical officer after consultation with the patient's general practitioner, and that the former may perform an operation if the patient be unable to afford the fee of the consultant.
8. No case of phthisis or infectious disease shall be admitted.

Sir WILLIAM MILLIGAN put forward a specimen budget to show that the institution would be a sound financial proposition, and suggested that the financing of such a "pay hospital" might be approached in one of three ways:—

1. By borrowing the whole of the money at 5 per cent. on the security of the building and of the parent institution, and creating a sinking fund of 1 per cent., which would redeem it in 30¾ years.
2. One-half of the money required might be borrowed at 5 per cent. on the value of the building, and the other half by the issue of 6 per cent. cumulative preference shares and ordinary shares; or
3. The formation of a limited liability company with a capital of £50,000, divided into 30,000 £1 6 per cent. cumulative preference shares and 20,000 £1 ordinary shares, the whole of the ordinary shares to be held by the parent hospital.

As the subsequent discussion emphasised, the success of such a scheme depends entirely on the active coöperation of the medical profession. Whether this would be obtained seems to depend mainly on the wording of Clauses 2 and 6. The general practitioner is to be "allowed access" to his patients while in hospital, presumably as a friend, for the satisfaction of his scientific or personal interest in the case. It is doubtful whether there is anywhere in the world a more disinterested body of men than the general practitioners, but no amount of scientific enthusiasm or devoted service will support and educate a growing family. It is on these middle-class patients that the practitioner is dependent for his living; he can scarcely be expected to encourage a scheme that will take these patients off his visiting list as soon as he has diagnosed any serious malady. Nor can the patient be expected to desire the continued attendance of the practitioner when he finds himself under the care of a resident medical officer, whose competency is vouched for by his position in a great organisation. The "family doctor" is the backbone of the medical profession, and though he may have many failings in the eyes of the specialist and the research worker, it is by his improvement and not by his abolition that the public health will best be served. Some such scheme as that suggested by Sir William Milligan is undoubtedly called for, but it will have a greater hope of successful life if the general practitioner be left in charge of his patient as he would be in a nursing home, with the enormous advantage to everyone of coöperation with the hospital staff. The sisters in charge of nursing homes find no insuperable difficulty in the absence of a resident medical officer and the attendance of a number of general practitioners; there is no reason why the same working should not apply to the "pay hospital" The harassed practitioner fervently desires to see the establishment of some institutional treatment that shall be within the means of his poorer paying patients, but he very rightly and properly desires that any such scheme shall leave him in responsible charge of the conduct of the case.

WELFARE OF THE BLIND.

The fifth annual report of the Advisory Committee on the Welfare of the Blind indicates that further progress has been made towards the solution of the problem of making life tolerable for this unfortunate class of the community. Since the qualifying age for the receipt of the old age pension was lowered for blind people from 70 to 50, 85 per cent. of those so qualified are in receipt of the pension, the remaining 15 per cent. being presumably in possession of some private means. Schemes for promoting the welfare of blind persons have now been presented by the 146 local authorities concerned. All have been accepted and the great majority are in full operation. Of the total number of blind in England and Wales—36,518—more than 32,000 are over 16 years of age, and of these about one-quarter are actually employed either in workshops for the blind or as "home workers," the definition of which term appears to be somewhat elastic. The present report records some progress in the efforts made to obtain employment for blind persons in ordinary industrial concerns and in work normally performed by sighted persons. So far as the more skilled processes go this has not been found to be practicable, but a number of firms in the Midlands have expressed their willingness to give blind persons a trial period of employment on such operations as the preparing and labelling of tins, stringing tennis rackets, taping, smearing and packing of golf balls, armature winding, cardboard box making, gauging lamp glasses, assembling and packing cycle bells, and the sorting of hemp. As it is never expected that the average blind man can earn a living wage, the report recommends that voluntary agencies should receive official grants of not more than £20 per annum per head in respect of blind persons employed in ordinary factories and workshops.

There remain nearly 60 per cent. of the blind in the country who are classified as unemployable, some of them mental or physical defectives or afflicted with deafness, the majority of them having become blind in adult life, after which the difficulties of training for suitable employment are, of course, indefinitely increased. A great advance in the provision of assistance for unemployables has been made through the institution of the home-teaching service. At the present time there are 111 sighted and 159 blind or partially blind home-teachers employed by the various agencies and local authorities in the country in this capacity. Besides giving instruction in the reading of embossed literature and in simple pastime industries, they are expected to be friend and adviser to their pupils in domestic and social matters, and all those who are newly appointed are required to obtain the home-teachers' certificate of the College of Teachers of the Blind within two years. To well-educated young women with a natural ability for social welfare work the report commends this service as providing a useful field of work with fair remuneration, in which their efforts would be abundantly repaid by the results achieved. The report shows that consequent upon the passing of the Blind Persons Act of 1920 there has been a very substantial improvement in the general circumstances of the blind in the country. The triple partnership of the voluntary agencies, local authorities, and the State in dealing with the welfare of the blind has been more than justified. One matter is touched on in the report which needs to be emphasised. At present, owing to the lack of suitable schools for the partially blind, a good many of these children, more especially the high myopes, are being educated in blind schools, whereas it would be far more to their advantage, and ultimately an economy to the State, if schools or classes of the type initiated by the London County Council were made more generally available. The after-care of this class falls more properly within the sphere of the juvenile employment committees of local education authorities. The Board of Education are rightly proposing to press for the provision of further special accommodation for this class of children.

THE RADIOLOGY CONGRESS.

The International Congress of Radiology which is being held in London this week opened very pleasantly on Tuesday evening, June 30th, with a reception to the delegates and their friends, given by Dr. C. Thurstan Holland, the President, at the House of the Royal Society of Medicine, 1, Wimpole-street. A large number of guests was present, forming a truly international gathering. In the library an interesting display of old books dealing with medical electricity was on view, and in the Barnes Hall Dr. Murray Levick entertained the company with a description of penguin life in the Antarctic, illustrated with lime-light views taken by himself. This was followed by a cinematographic film of certain tuberculous conditions, demonstrated by Dr. Lewis Gregory Cole, of New York. The subsequent meetings of the Congress are being held in the Central Hall, Westminster, commencing with a discussion on international units and standards for X ray work, and concluding on Saturday, July 4th, with a meeting of the international delegates to consider the formation of an international committee. The work of the Congress is divided into three sections, radiology, physics, and actino-therapy respectively, and with regard to the latter branch we would draw attention to the paper on a Light Department in a Hospital for Surgical Tuberculosis, by Sir Henry Gauvain, in our present issue. This Congress has been promoted and organised jointly by three societies in Great Britain, all interested in similar objects, the Rontgen Society, the Electro-therapeutics Section of the Royal Society of Medicine, and the British Institute of Radiology, and it is a source of gratification to British radiologists that they have had promises of world-wide support. The Congress itself will determine whether this meeting will form the first of a regular periodic series of such meetings, but however that may be, we feel assured that the laborious work carried out by Dr. Holland, Dr. Stanley Melville (General Secretary), and the organising committee will prove a source of pleasure, interest, and profit to all whose interest lies in developing radiology—the infant prodigy of medicine,

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF PHYSICIANS OF LONDON: CENTENARY CELEBRATION OF THE PRESENT COLLEGE.

A CONVERSAZIONE was held at the House of the Royal College of Physicians on the evening of June 25th, to celebrate the centenary of the occupation of the present building of the College. The guests were received by the President, Sir Humphry Rolleston, and Lady Rolleston. A large number of Fellows, Members, and ladies attended. The College buildings are admirably adapted for a reception of this kind and the valuable possessions of the College were shown to great advantage. The library, where the President received the Fellows and guests, is a large and attractive room. The new lighting shows its contents to advantage, including the beautiful mace, which is one of the chief of the College treasures.

An interesting historical note was attached to the programme given to each guest on arrival. From this we learn that the Royal College of Physicians was founded by Thomas Linacre, the famous scholar, who obtained from King Henry VIII. a Royal Charter, dated Sept. 23rd, 1518, granting certain powers to the College for the purpose of controlling those who practised medicine in the City of London and seven miles around. The powers of the College were extended by later charters so that authority was exercised over all those who practised medicine in England, with the exception of doctors of medicine of Oxford and Cambridge Universities. Thomas Linacre was elected the first President, and five other physicians were named as Fellows of the College with power to add to their number. The first meetings of the College, for the transaction of business, were held in Linacre's house in Knightrider-street, in the City, and here the College remained until 1614, when a new house was provided at Amen Corner, on the site of the present House of the Canons Residentiary of St. Paul's. This College House was burned down in the Great Fire of 1666, and in 1674 the College removed to a new building in Warwick-lane, in the City, which had been built from the designs of Sir Christopher Wren. Here it remained until 1825, when it removed to the present building. The library contains about 40,000 volumes, of which more than 4000 were printed before the year 1600. The collection is not confined to medical works alone, for it contains sections comprising early editions of the classics, theology, law, and the sciences. The College possesses 112 portraits in oil of distinguished Fellows, and the collection is representative of many of the portrait painters in England during the last three centuries. These are placed in the large library, the Censors' room, the reading room, and on the staircase. The handsome panelling to be seen in the Censors' room dates from the year 1674, and was removed from the College in Warwick-lane, where it was placed through the munificence of Dr. Baldwin Hamey. The portraits of past Presidents and Fellows form a most striking and interesting collection. They are shown to great advantage in the library, Censors' room, reading room, and hall of the College. Among these, those painted by Gainsborough, Reynolds, and Romney are specially worthy of notice. There is also a portrait by Van Dyke and a painting by Zoffany.

Among the entertainments there was a fine exhibition of cinematograph films illustrating nature-study. It was pleasant to hear that these were of British origin. An interesting programme of music was given by the Vale Lane Sextette. The engraved portraits of Fellows of the College on view in the small library and book-store were well chosen and attracted a good deal of attention.

The conversazione was a most successful one. This notable historic incident in the history of the College was, by common consent, very suitably commemorated, and those present spent an interesting and instructive evening. The President and those responsible for the arrangements are greatly to be congratulated on the success of a very interesting commemorative function.

THE USE OF ARSENIC IN PUERPERAL FEVER.

THE use of arsenical salts in puerperal infection was the subject of a paper by Marbais at the Congress of Strasbourg in 1923. Dr. H. Lapervenche has now published a record of 28 cases treated in this way at the obstetric clinic in Bordeaux. The salts employed were sulpharsenol (Pluchon) and novarsenobenzol (Billon), which were shown to have a strong bactericidal action on streptococci in vitro and in rabbits. They can be used prophylactically in cases where the labour has been prolonged and infection is suspected. The only contra-indications are the presence of serious hepatic trouble and uræmia, cancer, and what the author calls "bacillaires," presumably the subjects of chronic bacterial infections. It is usual to allow a day to elapse between the first and second injections, and then to give injections on two successive days with an interval of one day between. The urine should be watched for albumin. Intravenous or subcutaneous injections of 0·1 gr. of N.A.B. or 0·06 gr. of sulpharsenol is the initial dose, and subsequent injections should not rise higher than 0·15 gr. of N.A.B. and 0·12 gr. of sulpharsenol. No evil results were noted beyond the local discomfort of the injection, and the results were most gratifying, the fever being controlled by the drug. These cases were streptococcal, and syphilis was excluded by the Wassermann reaction. The method seems worthy of a more extended trial.

JAMES MEASE.

IN the number of *Annals of Medical History*, published in March, 1925, being No. 1 of Vol. VII., Dr. William Snow Miller, of Wisconsin, reprints a paper read before the Medical History Seminar of the University of Wisconsin in November, 1923. The subject of the paper is Dr. James Mease, who is interesting as being the author of the first contribution of note upon hydrophobia published in America. From another point of view he is of interest to ourselves as having fallen foul of William Cobbett (an easy thing to do), and Cobbett, as readers may know, was a good friend to THE LANCET in early days. Mease graduated in medicine in 1792, being one of the first seven graduates from the medical department of the University of Pennsylvania. This University had arisen after sundry vicissitudes out of the College of Philadelphia, which, in its turn, was begotten by a pamphlet written by Benjamin Franklin in 1749. Mease's paper upon hydrophobia was first published in the *American Museum* in 1790, and this paper was subsequently elaborated into his thesis for the doctorate. Dr. Miller gives many quotations from the thesis which show that Mease was in advance of his time in his views on the disease. He maintains that disease only arises from a "poison of a peculiar nature in the saliva of a rabid animal, belonging to the genus *canis*." He also is of opinion that the poison, to manifest its effects, must find entrance to the body through a wound. As to treatment he recommended excision of the bitten place, if possible, together with the cautery before any symptoms had appeared. After they appeared he considered any treatment useless. The year after his graduation—namely, in 1793—there was a serious epidemic of yellow fever in Philadelphia during which Mease was attacked and was treated by Rush, being bled to the extent of 75 oz. in five days. He recovered and was appointed port medical officer of Philadelphia. Benjamin Rush, the professor of clinical medicine in the University, treated the fever by free purgation and copious bleeding, methods which were warmly supported by Mease, although other medical men disapproved of them. These dissenters found a mouthpiece in Cobbett, who published a bitter attack upon Rush in *Peter Porcupine's Gazette*, which led to an action for libel in which Cobbett was cast in 5000 dollars damages. Mease gave evidence in favour of Rush and this led to an attack on him by Cobbett in the opening number of his other paper the *Rush Light*. Like most people in authority Mease also got into trouble with certain persons owing to his allowing vessels to proceed from Philadelphia to Burlington without performing quarantine, and Dr. Miller gives a full account of the quarrels. Mease was not only a physician, but an active member of Philadelphia society, giving generous support to that city's many intellectual and humanitarian institutions. He married in 1800 Sarah Butler, by whom he had two daughters and three sons. The sons, on attaining the age of 16, changed their name to Butler under their grandfather's will and one of them, Pierce, married Fanny Kemble. Mease died in Philadelphia in 1846.

FRAMBŒSIAL OSTEITIS.

THE remarkable condition called "goundou" or "henpuye," and characterised by bony outgrowths on the sides of the nose, has been recognised as prevalent in parts of tropical Africa since MacAlister in 1882 noted the existence of "horned men in Africa." In 1900 Chalmers described the disease on the Gold Coast in THE LANCET[1] under the name of henpuye, and reported five cases, though he doubtless saw many others and operated on several; he was the first to attribute its causation to framboesia or yaws. Major Botreau-Roussel, of the French Colonial Army Medical Service, has now published[2] a most complete work on this curious affection. After four years' residence on the Ivory Coast, during which time he only saw one case, chance brought him two patients, on whom he operated with success; as a result more and more patients came for treatment, until he had seen 180 cases and operated on 113. The outgrowths on the nose limit the field of vision and, in the more extreme cases, to such an extent as seriously to handicap the sufferer in the struggle for existence, which is a severe one in these regions; and the author believes that many of these unfortunates are quietly destroyed by their relatives, who cannot afford to feed a useless member of society. It is not surprising, therefore, that the natives should come from long distances to be relieved of their disability by operation.

From his unequalled experience of the disease, Major Botreau-Roussel has formed an opinion on the following points. The lesions of the face are the most striking but not the most frequent symptom of an osteitis which may attack the greater part of the skeleton, the long bones, and especially the tibia, being the most commonly affected. The osteitis is definitely caused by framboesia, and usually begins either during or shortly after the framboesial eruption. Patients suffering from the osteitis are refractory to inoculation with framboesia; in the one case in which the onset of the osteitis was observed, at the sixth month of the framboesial eruption, both the bony and cutaneous lesions yielded to treatment by novarsenobenzol. The author makes some interesting observations on the geographical distribution of the disease; commonest on the Gold and Ivory Coasts, it occurs throughout tropical Africa, and has been found in the West Indies, Central and South America, China, Sumatra, Malay, and New Guinea. No case has been reported from Europe, but the author believes that some cases labelled leontiasis ossea would have been called "goundou" had they occurred in the tropics; he concludes that true leontiasis is due to hereditary syphilis, and that the *Treponema pallidum* and the *Treponema pertenue*, the causative organism of yaws, are able to produce very similar lesions.

Major Botreau-Roussel's work is profusely illustrated and forms a notable contribution to the study of an important tropical disease.

INTERNATIONALISM AND MEDICINE.

WE have received from Dr. A. A. Warden, of Paris, an interesting communication under this title, in which he points to the recent visit to Europe of our American colleagues as a proof of the spread of the feeling that medicine is an international affair. The view has been expressed so often and so fully in these columns that we need not reproduce Dr. Warden's words, while we agree with him that medicine in its national and international relations occupies no different place to that occupied by science, literature, and art. All developments of these immediately add to the common stock of wisdom of the world in a degree proportionate to the dissemination of new work. But Dr. Warden singles out medicine as the great activity which might promote the cause of international peace if (and it is a large "if") all those who practise it should refuse to have anything to do with the conduct of a war. There is both truth and ingenuity in his argument that the services of medicine, while they alleviate the horrors of war, may also prolong those horrors by maintaining a continuous supply of fighting men and, through the prevention of epidemics, a continuous supply also of those who minister to the forces. This position has been pointed out before, but we doubt if it would act as a common inducement to medical men all over the world not to place their services at the disposal of their countries. Dr. Warden suggests that this is a question which might well be submitted to an international gathering of medical men, and brings the idea forward in order to ascertain how far it receives support in this country.

INOCULATION AGAINST CATTLE DISEASE IN SOUTH AFRICA.

MR. L. E. W. Bevan, M.R.C.V.S., has been doing good work in Southern Rhodesia, and in reports[1] to the Secretary to the Minister of Agriculture and Lands, Salisbury, he gives an account of his findings. He has devised a special vaccine for use against infectious abortion of cattle which he names "devitalised vaccine." His aim has been to retain in the vaccine only those elements required to call out in the treated animal the maximum quantity of specific antibodies. The particular virtue claimed for the vaccine is that it can be applied without risk during pregnancy, so that the resistance to infection is maintained until the danger of infection has gone by. Reports received from cattle owners who have used the vaccine are encouraging, and from hundreds of careful experiments and observations at the laboratory the efficacy of the vaccine has been verified. Mr. Bevan thinks that the best plan of campaign in dealing with an outbreak of infectious abortion is to seek out and eliminate the source of infection, to disinfect cow-sheds, kraals, and infected watering-places, to get rid of non-breeding cows and those constantly returning to the bull, to test all bulls and remove reactors, and to vaccinate all cows in danger of becoming infected. He regards it as essential to continue this policy over a *series of years*. Infectious abortion of cattle merits drastic treatment, both on its own account and because of its apparent infectivity to man. Out of 80 cases of Malta fever admitted to Rhodesian hospitals at least one-half came from areas where goat's milk had not been consumed but where infectious abortion existed at the time among the cattle. Mr. Bevan holds that the Rhodesian strain of *B. abortus* may be closely related to *M. melitensis*. In dealing with trypanosomiasis in cattle he has experimented with a preparation containing antimony and arsenic injected subcutaneously, a procedure which has in many cases enabled the owners of fly-struck cattle to carry on farming operations which they feared would have to be abandoned. Successful inoculation has also been practised against red-water and gall-sickness which are responsible for enormous losses among cattle. Protection of imported stock from infection by ticks until the immunity resulting from inoculation has time to develop is an important measure. Mr. Bevan has had the opportunity of dealing with disease on a far larger scale than veterinarians have in these isles, and has made good use of his opportunities.

NEW DRUGS FROM SOUTH AMERICA.

THE recent Mulford Biological Exploration of the Amazon basin, under the direction of Dr. H. H. Rusby, resulted in bringing back to the United States much interesting material, and amongst this were at least two drugs which, it is predicted, may have some therapeutic application. Caapi, the first of these, is the root and rhizome of a woody vine, *Banisteria caapi*, which grows in the central portion of the Amazon basin. The plant belongs to the *Malpighiaceæ*, a large family of tropical woody climbers, but no other member of this family is known to possess similar medicinal properties. The use of this drug by the natives in Colombia was first described by Humboldt and Spruce, and, later, two German explorers, Weiss and Schmidt, made extensive observations on its use and obtained photographs of natives under its influence, but their researches were apparently never published. Dr. Rusby heard of the plant from these workers, and with the aid of his photographer, Mr. Gordon MacCreagh, obtained material for study. In another part of South America Dr. O. E. White discovered the drug in use under the name of "ayahasco." In Bolivia it appears that caapi is used mainly as a stimulating beverage, similar to tea and coffee; but in Colombia the drug is used for the specific purpose of giving courage and fortitude in facing danger and enduring suffering. Dr. Rusby has given an account of the effect of this drug, from which the following passage is taken[1]:—

> "Within a very short time after drinking the decoction, there is a powerful effect on the nervous system and on the circulation. The cutaneous circulation is checked, as manifested by a strong pallor. The subject is restless, and occupies a standing position. There is an intensely anxious or fixed expression to the countenance, and there are convulsive tremors. This condition lasts but a few minutes and is followed by a violent reaction, in which the blood rushes to the surface and the man becomes highly or even violently active. Fear, and even prudence, is entirely destroyed and he becomes extremely active muscularly. He is ready to fight anything and everybody, or any number of enemies and suffering is disregarded. He rushes about and seeks an enemy with utmost eagerness. This condition lasts for hours, and is followed by more or less exhaustion and somnolence. The nature of this somnolence is in doubt. Some accounts indicate it is a narcotic effect and that there are unnatural dreams and visions. Others indicate that it is the natural reaction following weariness or exhaustion."

A chemical examination of caapi has shown that it contains three, and possibly four, alkaloids, one of which is closely related to morphine. Three alkaloids have been separated with great difficulty—a phenolic alkaloid, a non-phenolic alkaloid forming a hydrochloride which is only soluble with difficulty, and the third, a non-phenolic alkaloid forming a more readily soluble hydrochloride.

The other drug which appears to be of pharmacological interest is extracted by the Indians of Central Bolivia by boiling portions of a plant known as miré (pronounced mee-ray). The plant is said to be a member of the nightshade family, and is employed by the natives as a muscular paralysant and remedy for cutaneous parasites. In full doses the natives report that it produces paralysis of all the voluntary muscles without any disturbance of sensation or intellect, while a profuse perspiration of the cold type is produced, and this perspiration is said to be capable of destroying all cutaneous parasites. Animal experiments carried out by Dr. T. S. Githens[2] indicate that miré causes paralysis of the voluntary muscles by an action on the spinal cord, a stimulation of the peripheral motor apparatus, resulting in twitching of the muscles, a stimulation of the salivary and sweat mechanisms and sometimes of peristalsis, while the heart is slowed, probably from vagal stimulation.

BRITISH MEDICAL ASSOCIATION: COMING EVENTS.

DURING the present month two important events in the life of the Association will take place. The first is the opening, on Monday, July 13th, of the Association's new premises, designed by Sir Edwin Lutyens, R.A., in Tavistock-square, London. The ceremony will be performed by H.M. the King, who will be accompanied by H.M. the Queen, and the Archbishop of Canterbury will dedicate and open the Memorial Gates erected by the Association as a tribute to the 574 members who fell in the Great War. The Reception Committee has not found it possible to get into touch with the relatives of all these deceased members and would, we understand, welcome application for tickets from any who have not been reached. The gathering will include delegates of medical bodies not only from Great Britain but from the dominions, colonies, and from foreign countries. The second event is the ninety-third annual meeting of the Association, to be held in Bath from Tuesday, July 21st, to Friday, the 24th, under the presidency of Dr. Frederick George Thomson, physician to the Royal United Hospital. The presidential address will be given on Tuesday evening, and the annual exhibition of surgical appliances, foods, drugs, and books will be officially opened on the same day. The various scientific sections meet during the forenoons of Wednesday, Thursday, and Friday, July 22nd–24th. The annual dinner will take place on Thursday, July 23rd; and the popular lecture will be delivered by Sir W. H. Bragg, F.R.S., on Friday, July 24th, at 8 P.M. The annual Representative Meeting will begin on Friday, July 17th, and be continued on the three following week-days. The statutory annual general meeting will be held on July 21st, at 2 P.M., and the conference of secretaries on Wednesday, July 22nd, on the evening of which day the secretaries' dinner will take place. Saturday, July 25th, will be given up to excursions to places of interest in the neighbourhood. The honorary local general secretary for the annual meeting is Mr. W. G. Mumford, F.R.C.S., to be addressed at the B.M.A. Committee Rooms, Bath, where he will be assisted by Dr. R. G. Gordon.

THE ROYAL MEDICAL BENEVOLENT FUND GUILD.

THE scanty support given to the Royal Medical Benevolent Fund is a grave blot on the escutcheon of the medical profession. In order to assist this most deserving charity a number of ladies formed themselves in 1909 into a Guild for the purpose of soliciting additional subscriptions and assisting the work of the fund by personal service. The fifteenth annual report of the Guild records a successful year of work. So rapidly are the activities growing that it has been found necessary to rent a permanent office at 58, Great Marlborough-street. The established branches are in a satisfactory condition and money has been raised by dances, bridge parties, American teas, bazaars, and other special efforts. There are, however, many provincial towns where no branch has yet been formed and it is most desirable that the work should be extended to every part of the country. One of the most engaging activities of the Guild is the "Father Christmas branch," which sends Christmas gifts to the sad cases on its books, sweets and books for the children, and money for the elderly. It is at the festive season that the burden of a hard life becomes more bitter, and a small remembrance such as the Guild is able to provide brings a feeling of joy quite disproportionate to the value of the gift. The heavy rentals demanded for single rooms as well as the general increase in cost of living and crowding of the labour market has reduced many of these people to real starvation; their appeals are almost always for work, but modern conditions afford little hope of livelihood to the untrained or partially-trained and elderly worker. The Guild allows money grants to the aged, the sick, and for special emergencies, such as removal, purchase of surgical appliances, spectacles or dentures, holidays, and the acquisition of some means of livelihood such as a typewriter. The fundamental principle underlying the work is to help people to help themselves. Scarcely more pathetic, but still graver from the point of view of the community, are the young children whose education cannot be completed owing to the death of their father. Much valuable service would be lost to the State if the Guild were not able to save these children from the lives of uncongenial and unproductive labour into which poverty would force them. The attention of practitioners and their wives is drawn to the value of the work being done by this Guild. The Secretary is Miss Thomson, 60, South Molton-street, W. 1.

THE SECRETARYSHIP OF THE ROYAL SOCIETY OF MEDICINE.

AT its last meeting the Council of the Royal Society of Medicine selected a successor to Sir John MacAlister from a large number of applicants, the choice falling upon Mr. Geoffrey R. Edwards, B.A. Camb. Mr. Edwards was educated at St. Paul's School and St. John's College, Cambridge. He studied in Germany in order to qualify for the Woods and Forests Department of the Indian Civil Service, and continued this work in India. On his return to this country he joined the Royal Air Force as a pilot, was wounded, and had to alight in enemy country, entailing an imprisonment of 14 months in Germany. Subsequently, Mr. Edwards served on the Repatriation Commission in Germany and on the Inter-Allied Aeronautical Commission of Control. When finally demobilised he obtained the appointment of assistant secretary to the National Physical Laboratory, Teddington, where he had considerable experience in library and editorial work, in organisation, and in receiving. Mr. Edwards has travelled in most European countries and speaks French and German. He takes up the duties for which he is so well qualified on Sept. 1st next, and we wish him well in a position of great importance and interest. We are glad to learn that the Society has decided to mark Sir John MacAlister's retirement by appealing for funds to raise a memorial to his great work for medicine over a period of 38 years. Fellows of the Society will be glad to have the opportunity of constituting a permanent memorial of the man to whom the very existence of the Society is chiefly due. The proposal is to ask Sir John MacAlister to sit for his portrait, to be rendered in oil or stone.

THE JOHNSTON-LAVIS GEOPHYSICAL BEQUEST.

THE late Dr. H. J. Johnston-Lavis, who was both a medical man and a distinguished geologist, bequeathed to University College, London, his geophysical collection of some 20,000 specimens and a remarkable library of books and pictures relating to volcanic phenomena. These have been housed at 184, Gower-street, a few doors from University College, where the collection was formally opened on June 25th by Sir Henry Miers, F.R.S., Vice-Chancellor of the University of Manchester. Sir John Rose Bradford presided, and among those present was Dr. de Lavis-Trafford, the son of the donor, who is qualified in medicine in France. Johnston-Lavis, who was descended from a Huguenot family, "de Lévis," received his primary education at the Grammar School, Iver, Bucks. While there, the story goes, a school-fellow threw a stone at him. Young Johnston-Lavis, although in pain, examined the stone with curiosity, and further investigation showed the missile to be a fossil echinoderm. This event stimulated his interest in geology, and the stone formed the first specimen in his collection. In 1878 he became a student at University College, studied medicine at St. Mary's Hospital, and qualified with the M.R.C.S. in 1878. While a medical student all his leisure was devoted to geological studies, and at 18 he joined the Geologists' Association, in the following year became a member of the Geological Society, and at the age of 20 published his first geological paper. The value of geology to medicine was shown in his essay, which gained the Parkin Prize of the Royal College of Physicians of Edinburgh in 1914. This discussed the physics and chemistry of volcanic eruption and the physical effects of eruptions on human beings and animals. For many years Johnston-Lavis was Professor of Vulcanology in the Royal University of Naples and, as Prof. Miers pointed out, he was the very embodiment of the scientific spirit in all the work which he did. The gift forms a permanent expression of the donor's affection for the College and the University.

BENJAMIN BROADBENT.

Benjamin Broadbent, who died on June 25th at the age of 75, was a younger brother of the late Sir William Broadbent and, like him, a forceful person. He will be remembered as a pioneer in child welfare work. For many years chairman of the Huddersfield Health Committee, he entered with enthusiasm into the efforts of the medical officer of health, Dr. S. G. Moore, to save the lives of infants dying from preventable causes in the borough. In 1904 Mr. Broadbent accepted the civic chair for the definite reason that he believed it would give him greater scope for combating infant mortality. He offered a gift of £1, secured by a promissory note, to every baby born in Longwood (where his woollen mills were situated) during his year of office, who was still alive at the end of 12 months, the object being to ascertain where births had taken place, so that they might be followed up. During the year 112 infants were born in that ward, of whom only four failed to claim their birthday present; at the end of ten years 98 were still alive, and only seven were known to have died. The first promissory note was taken to the house by Miss Broadbent, and thus began a system of voluntary home visiting. In the following year the Huddersfield and District Public Health Union was instituted, with Mr. Broadbent as president. This Union, which secured the help of more than 100 volunteers, worked in close coöperation with the Public Health Department. A fee of 1s. offered for any notification of birth received within two days was largely successful, but failed in just those cases where it was most needed, and it was chiefly due to the representations made by Mr. Broadbent and Dr. Moore that in 1906 compulsory notification of births was introduced by Act of Parliament. A fundamental aim of Mr. Broadbent's work for child welfare was to keep mother and child together in the home, and to give help to both. His influence had much weight in the establishment of the National Association for the Prevention of Infant Mortality, for which he drafted the constitution. Again, it was on Mr. Broadbent's suggestion that, at a Mansion House Conference in 1917, it was decided to form a small committee to act in conjunction with Lord Rhondda to go into the question of a Ministry of Health. As recently as July, 1924, two striking articles appeared in the *Times* over the signature of Benjamin Broadbent, showing the results of a careful personal investigation into the "Ten Best Towns" for infant life. He was one of the speakers appointed to take part in the International Summer School to be held at Geneva in August of this year, when his subject was to have been Beginnings of Infant Welfare in Great Britain. Mr. Broadbent had the satisfaction, not granted to all pioneers, of seeing the fruits of his labour.

DENICOTINISED TOBACCO.

A NUMBER of people appear to be specially sensitive to the toxic effects of nicotine and its associated alkaloids contained in tobacco. Some of them are deterred from smoking at all; more of them smoke in excess of what they know to be good for their physical and mental efficiency. Dealers have endeavoured to meet the needs of these people by supplying tobacco from which the nicotine has been removed, in whole or in part. We published not long ago, at the request of a business firm, some analyses of the nicotine-content of tobacco treated with a view to reducing the percentage of nicotine. While the flavour and smoking quality remained, as far as we could ascertain, unchanged, it was possible to show that denicotinisation had taken place to the extent of 10 to 20 per cent. It must not, however, be assumed that every so-called " nicotine-free " tobacco placed on the market is in fact such, for a communication has recently been made[1] by Dr. L. Frank, scientific member of the Chief Health Office in Berlin, showing that the Chemical Institute attached to the Health Office was unable to confirm the withdrawal of nicotine from a number of tobacco samples so described. In two samples, in fact, the percentage of nicotine was higher in the treated than in the ordinary variety of tobacco as obtained from the same firm before treatment. The increase has a possible explanation in the greater dryness of the treated tobacco. The registered process of denicotinisation in this case appears to consist in the exposure of the tobacco, whether cigars or cigarettes, for a long time to a moist atmosphere, succeeded by a rapid rise of temperature to 150° C. in an exhaust chamber. Whether the unsuccess in the samples examined was to be ascribed to the process itself or to deficient technique in carrying it out Dr. Frank does not pretend to decide, but he does warn physicians not to recommend to their patients the use of cigars and cigarettes alleged to be denicotinised, without further evidence than the maker's assurance.

A RECEPTION will be held at the Royal College of Surgeons of England, Lincoln's Inn-fields, on Monday evening, July 13th, in connexion with the Convention of English-speaking Ophthalmological Societies. Fellows and Members of the College wishing to attend should apply to the Secretary, Mr. S. Forrest Cowell, at the College for cards of invitation before July 10th. The Convention meets from July 14th to July 16th, under the Presidency of Mr. Treacher Collins, Mr. C. B. Goulden (79, Portland-place, W.) being the General Secretary.

THE committee of the Torbay Hospital has received the sum of £100,000 from Mrs. Ella M. Rowcroft for the erection of the proposed hospital and chapel at Hengreave House. The site had already been purchased and this munificent gift will cover the whole cost of building, leaving the committee to raise only the sums for furnishing and equipment. Subscriptions have already been received and the donor hopes that the required amount may be completed before the hospital is opened, and also that there may be a sufficient surplus to form a substantial foundation for an endowment fund. The only conditions of the gift are that the chapel shall be erected in accordance with a plan and specification to be approved by the donor and shall contain a special window chosen by her, and that no vivisection or cognate treatment shall be permitted on the premises. An additional £6500 are provided to endow the stipend of the chaplain. A special effort is to be made to raise a further sum of £20,000 for endowment. The work is to be put in hand without delay.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXIX.—THE TREATMENT OF ABDOMINAL ADHESIONS.

THE scope of this paper is limited to a consideration of abdominal adhesions secondary to inflammatory processes or to operation, and does not include the various recognised types of colonic adhesions whose sites and appearances are constant—e.g., Jackson's membrane.

Inflammatory Adhesions.

In the first place, we must recognise that the formation of adhesions following inflammation of, or operation on, abdominal organs is a natural and life-saving process. It is only when these adhesions interfere with the normal functions that the patient seeks advice and treatment.

Adhesions which result from inflammation may cause severe symptoms of acute or subacute obstruction, and these are more liable to occur following a lesion in the lower abdomen. While in some patients symptoms supervene shortly after the acute attack, others may enjoy many years of unimpaired health before symptoms supervene. Cases are frequently seen in which the signs strongly suggest cancer of the colon and in which it is difficult to estimate the true significance of a history of " a bad attack of inflammation of the bowels " 15 to 20 years previously. Tuberculous adenitis of the mesentery is not an infrequent cause of acute or subacute obstruction, either by the formation of bands stretching across the abdominal cavity from the infected gland, or by actual attachment of the bowel to the gland. In cases of the latter type the prognosis ought to be guarded, because frequently the gland is acutely inflamed as the result of secondary infection from the bowel, and its close relationship to the large mesenteric vessels makes the development of thrombosis, embolism, or generalised infection fairly probable. The development of inflammatory adhesions tends to mask the signs and symptoms of the original lesion. For example, when a gastric or duodenal ulcer has become adherent to neighbouring organs the regularity of the appearance and disappearance of the pain in relation to the taking of food becomes less noticeable and is replaced by a continual discomfort or dragging pain. The seasonal remissions from pain also become incomplete or altogether absent.

Traumatic Adhesions.

After every abdominal operation a certain degree of peritoneal adhesions necessarily occurs. In the majority of cases no signs or symptoms result. In other cases discomfort develops and the surgeon must carefully consider whether at the primary operation an important lesion had been overlooked or has subsequently developed—e.g., a duodenal ulcer or gall-stones in a case on which appendicectomy has been performed—or whether in a neurasthenic patient operation has been performed on insufficient evidence owing to exaggeration of the original symptoms.

The "Adhesions Diathesis."

In the treatment of adhesions there is no difference between those of inflammatory or traumatic origin except, of course, that the former call for more urgent treatment of the primary focus, increase the difficulties at operation, and may cause a more prolonged convalescence. A great deal of experimental work has been done to try to elucidate the causes of postoperative adhesions and to devise methods for their prevention, but progress has been slow and unsatisfactory. Sepsis of low virulence, excessive trauma, and incomplete hæmostasis are without doubt important predisposing factors. In certain other cases an "adhesions diathesis" is said to be the cause. It is well known that certain individuals may suffer from acute and widespread peritonitis, that the abdomen may be opened, swabbed, packed, and drained without the development of any subsequent trouble from adhesions, while a slight and strictly limited operation in other cases may lead to prolonged crippling and suffering.

Points of Technique.

Strict attention to the established rules of surgical technique will greatly reduce the number of cases of "adhesions diathesis." Injury to the visceral and parietal peritoneum by mechanical or chemical means occurs all too easily, and in the subsequent repair harmful adhesions may result. It is now generally believed that the use of iodine or picric acid in the preparation of the skin is not conducive to the formation of adhesions if ordinary care be taken to protect the intestines from escaping outside the abdominal cavity. The use of strong disinfectants for lavage or for the moistening of packs is, however, to be strongly condemned. Undue exposure of the intestines to the air causes an injurious drying of the peritoneum and predisposes to the development of adhesions. Opinion is divided as to whether packs ought to be used dry or moistened in saline. In experimental work on guinea-pigs no marked difference between the two methods was noted, but the observations were not conclusive because in neither group did extensive adhesions develop. The use of rubber dam or jaconet to protect the intestines from the gauze is theoretically of advantage but mechanically is difficult to apply. All raw or bruised surfaces should be carefully and systematically covered by normal peritoneum whenever possible. The use of detached pieces of omentum to cover denuded surfaces is of doubtful value, as Mann[1] has shown that they quickly become converted into fibrous tissue with all its tendency to contraction and adhesion. The graft also shows very poor resistance to septic invasion. The use of undetached great omentum, the lesser omentum or ligamentum teres to cover raw surfaces is more likely to be of permanent benefit, but care must be taken that no undue strain is put upon these structures, or trouble will supervene, particularly after an operation in the lower abdomen, where a short omentum has been pulled down to protect the posterior surface of the wound.

Introduction of fluids such as liquid paraffin, vaseline, and gum acacia in gelatin into the abdominal cavity has not proved of practical value in the prevention of adhesions, nor has the introduction of oxygen after closure of the wound. In closing the abdomen care should be taken to evert the cut edges of the posterior rectus sheath and parietal peritoneum, thereby minimising the raw surface to which bowel may become adherent. Attempts have been made to overcome the harmful effects of adhesions by the early induction of peristalsis. Pituitary extract, eserine, and hormotone by hypodermic injection, and aperients injected into the bowel at operation or given by mouth soon after operation have been advocated. It is doubtful, however, if any of these methods can have a direct action on the bowel, which remains temporarily paralysed as the result of handling for about 24 hours; by this time the "glueing" together of coils of intestines by lymph will have laid the foundation of fibrous and permanent adhesions. All that can result is a drawing out of the fine adhesions before permanent deformity of the gut has occurred.

Relief of Post-Operative Pain and Discomfort.

Regulation of the bowels by suitable diet, regular habits, aided by mild non-irritating aperients, such as liquid paraffin, and massage, together with the assurance that the pains and aches are only temporary, will lead to a cure in many cases. In more resistant cases the use of heat in the form of hot fomentations or of "radiant heat" will be found to give considerable relief. Some patients complain of pain and dragging in the wound itself, and it is frequently difficult to determine whether the "fons et origo mali" is in the abdominal wall or is the pull of adherent intestine on its posterior aspect. The distinction may sometimes be made by observing whether or no the injection of novocaine into the abdominal wall gives immediate relief. If the point of pain or tenderness is well localised in the wound the use of a counter irritant—e.g., emplast. epispasticus or the injection of 20 to 40 c.cm. of normal saline into the abdominal wall—will be found to be very beneficial in some cases.

Operative Measures.—Should symptoms persist, and particularly if signs of acute obstruction develop, operation is called for and should on no account be postponed, in spite of the natural objection to a second operation. Very extensive interference with the blood-supply of the small intestine may rapidly and insidiously take place in a patient suffering from abdominal adhesions. Repeated attacks of vomiting, a tongue tending to be dry and coated, with perhaps some slight distension of the abdomen, are enough to justify exploration without waiting for other text-book symptoms of obstruction. A large incision should be made extending well beyond the limits of the scar of the previous operation in order to expose an area of peritoneum which has not been injured previously and to which it is unlikely the abdominal organs have become adherent. The opening into the peritoneal cavity should be made slowly under direct vision, unobscured by blood, and with a sharp knife in preference to scissors. By using this method injury to a knuckle of bowel which may, perchance, be adherent will be recognised before its lumen has been opened and another area further from the original wound selected. After the peritoneal cavity has been opened and the original wound reached, the cutting must be done with great care as a segment of intestine is frequently adherent to the posterior surface. In some cases a narrow band will be found to be the cause of the trouble and its ligature and division is all that is necessary. The more difficult cases, however, are those which show widespread adhesions, and it is often difficult to determine which of these is giving rise to trouble. Extensive "glueing" of the segments of the bowel does not cause symptoms, and one must look for the sharp angulation or narrowing which is the responsible factor. A loop of bowel showing dilatation and hypertrophy may be of great help in guiding one to the proper quarter. In the separation of adhesions I would again emphasise the advantage of a sharp knife used cautiously in place of scissors or any form of blunt dissector. All raw surfaces must be covered as well as possible and all bleeding stopped. Accidental punctures into the intestine or wounds involving its serous and muscular coats must be carefully closed, while in cases of extensive damage resection of the segment may be the quickest and most efficient method of treatment. Drainage should not be employed unless there has been persistent and uncontrollable oozing of blood or extensive soiling of the peritoneal cavity, as the presence of a foreign body predisposes to the formation of further adhesions.

WILLIAM ANDERSON, M.B. Aberd., F.R.C.S. Eng.,
Assistant to the Professor of Surgery, The University, Aberdeen; Assistant Surgeon, Royal Infirmary, Aberdeen.

UNIVERSITY OF BRISTOL.—The Markham Skerritt Memorial Prize has been awarded to Macdonald Critchley, M.D. Bristol. This prize was founded in memory of the late Dr. Markham Skerritt and is awarded every three years to that medical member of the University of Bristol who, in the opinion of the board of the medical faculty, has in the previous three years published the best original work in any branch of medical science. During 1924 Dr. Critchley has published the following papers: The Parkinsonian Syndrome (*Bristol Med.-Chir. Jour.*), Present Position of Parathyroid Therapy (*Pract.*), The Calcium Content of the Cerebro-spinal Fluid (with O'Flynn) (*Brain*).

Special Articles.

THE ANOPHELES MOSQUITO IN ENGLAND.

By A. W. Alcock, C.I.E., F.R.S.,
LT.-COL. I.M.S. (RETD.); LATE PROFESSOR OF MEDICAL ZOOLOGY IN THE UNIVERSITY OF LONDON.

Diffusion of knowledge of the fact that the malaria parasite undergoes in the anopheles mosquito those necessary stages of development that fit it for passage from one human being to another has not been accompanied by a corresponding understanding of the necessary circumstances in which this potential danger from the insect becomes realised in a general onset of malarial fever.

Imagining that both the anopheles and considerable numbers of relapsing malaria convalescents are recent introductions into these islands, and that the malefic powers of the insect are unconditioned, the public seems quite ready to believe the alarming prophecy that a general outbreak of malaria is impending in this country unless immediate steps be taken to exterminate the anopheles. It is necessary, therefore, that the public should understand that anopheles mosquitoes are as native to this country as the sparrows and the starlings; that malarial fever—known to our forefathers as "fever and ague"—is also native here, but from having been in former times extremely common is now almost extinct as a native disease, notwithstanding the constant re-introduction of malaria parasites in the blood of convalescents annually returning from India and other parts of the tropical dominions; and that this gradual process of extinguishing malaria was carried well the right side of the public safety-point without any attempts at exterminating the anopheles mosquitoes, and, indeed, long before the malaria parasite and its vital associations with a mosquito of any sort had been discovered. It is advisable, in short, that the public should be taught as a most conspicuous illustration of the value of sanitation, how, in a country that possesses an efficient sanitary administration, a creature so potentially dangerous but so difficult to exterminate as the anopheles mosquito can be permitted to exist, *in its proper natural stations*, without menace to the public health.

Native Village and Modern City.

That the nature of the sanitary environment is the main factor in determining the influence of a potentially dangerous species of anopheles upon the public health is easiest understood by comparing an unsophisticated native village with a modern Anglicised city—both situated in a malarious tropical province—by comparing, for instance, an ordinary village in Lower Bengal with the European quarter of Calcutta. The native village, more or less obstructed by jungly growth, stands on soil that for much of the year is waterlogged; the surface of the ground is broken, so that, as there is no drainage, every chance hollow may be a temporary nursery of anopheles during the rainy season; moreover, there also are innumerable permanent breeding-grounds. Above all, the clusters of thatched, cow-dung-plastered huts and *baris*—damp, dark, ill-ventilated—in which the most part of the people live, are ideal haunts and permanent harbourage for the adult anopheles. In such conditions the villagers and the anopheles live together in close intimacy, and the swiftly succeeding swarms of anopheles must always be sucking the blood of infected human beings and returning the infection indiscriminately to the village population.

The state of Calcutta at the end of the eighteenth century, as described by Busteed, seems to have been almost worse than that of a Bengal village. The houses of the Europeans may have been large, but they had not glazed windows, and the entire settlement "at this time stood in what was little better than an undrained swamp, in the immediate vicinity of a malarious jungle . . . and the ditch surrounding it was . . . an open cloaca." Even into the early part of the nineteenth century the place was known as a white man's grave. But before the end of the nineteenth century the European quarter of Calcutta, so far as the essentials of sanitation are concerned, had attained the standards of a high civilisation: insanitary native *bustees* had been cleared away, ways and spaces were well kept, surface drainage was sufficient, and the drainage of the neighbouring *maidan* was magnificent. The tanks, or reservoirs, which in early days had been the water-supply of the city, still remained as more or less ornamental relics, and still served as breeding-grounds for plenty of anopheles mosquitoes, and among them the dangerous *Anopheles funestus*; but dry and well-ventilated rooms are not attractive to anopheles, and these insects did not make their way into well-constructed houses, so that good authorities doubted whether primary cases of malarial fever *originated* any longer in the European quarter of Calcutta. We must consider what is likely to happen to such insects as still might get into rooms so unsuitable to their taste. Are they as likely to bite human beings—or to light upon an infected human being—as they would be in a native village? Are they likely to remain in a situation so inhospitable long enough to develop an infection (10 to 20 days) if it were acquired? Such a favouring concurrence of events is likely to happen only where large numbers of anopheles and large numbers of infected human beings exist for a considerable time in constant association in an environment that suits the insect.

Story of Malaria in England.

To estimate present-day possibilities of danger from our native British anopheles we have to consider the history of malaria in England in the light of the foregoing comparison. The result will be to show that in the old pre-sanitary days, when the state even of cities like London was almost as bad as that of an Indian village, "fever and ague" was extremely common here, and that with the progress of sanitation it disappeared except as an insignificant localism—and all in entire ignorance and unconcern of the anopheles mosquito.

It is doubtful whether it is now generally realised how common malaria was in this country—and even in London—in the days of our forefathers. The bill of mortality for the London area for the year 1665 included 5257 deaths from "fever and ague" in a population that must have been less than one-tenth of what it is now; and if it be objected that this was the year of the Great Plague, when deaths from that disease might have been deliberately concealed under a less fearful name, it may be replied, on the other hand, that the spring and summer of that year were seasons of a phenomenal drought that would have played havoc with mosquitoes. But there is no need to search for inaccessible records; books familiar to every educated Englishman—the "Canterbury Tales," the plays of Shakespeare, the diaries of Pepys and of Evelyn, and Swift's "Journal to Stella"—give us plenty of information on the subject. An evil that comes most readily to Chaucer's imagination in "The Nun Priest's Tale" is a "fevere *terciane, or an agu*, that may be your bane." What with direct speech and metaphor there are more than a dozen striking references to ague and quotidian shakings in Shakespeare's most familiar plays. Pepys's business was several times hindered by "my lord's" ague, and one of his merry parties was interrupted by the ague-fit of a lady guest. Evelyn has a good deal to say about Charles the Second's ague; he tells of one dangerous attack when the king insisted on having the new remedy "quinquina"; he describes his own little son's death at Deptford from "a quartan ague"; and he gives a full account of the *popular* cure—bathing the legs in milk as hot as could be borne and drinking carduus posset—by which he cut short one of his own attacks of ague. Swift, writing in 1711 from Chelsea, tells Stella that "people here are troubled with ague . . . which is a very common disease here," even Queen Anne and Lady Masham not escaping; and he chuckles over his pun on the fellow who "pretends to cure agues, and has set out a sign, and spells it 'egoes' . . . but I was sure [the cure] was not by a *spell.*"

Change in Sanitary Environment.

Again it is doubtful whether a generation familiarised with sanitary conventions from its cradle realises what our forefathers endured in consequence of their ignorance and indifference in matters of sanitation. What London itself was like in the latter part of the seventeenth century—and there is no good reason for supposing that it was worse than other British towns—is tersely described in Mr. W. G. Bell's recently published book on "The Great Plague in London in 1665"; the description well suffices to explain the prevalence of fever and ague at that time. In the absence of drainage there must have been a profusion of temporary breeding-places for the anopheles among the crooked, obstructed, unpaved ways, and domestic wells and ill-kept streams must have provided permanent breeding-grounds in plenty; while dark, damp, ill-ventilated rooms, in houses constructed largely of wood and confined by accumulations of garbage, must have been attractive harbours for the adult anopheles.

When the sanitary environment of the present time is contrasted with this domestic and civic indifference of those pre-sanitary days it is easy to understand how an intimacy between humanity and anophelinity has been broken, and how, in consequence, malaria has disappeared from this country, except here and there within the limits of a few scattered and rather "wild" areas whence a case of indigenous malaria is occasionally reported as an interesting curiosity. With this conquest over malaria there has not been a concurrent subjugation of the anopheles. Those now innocuous insects may not perhaps exist to-day in the City of London, but all the three British species—*maculipennis*, *bifurcatus*, and *plumbeus*, all of them susceptible to malarial infection—exist in fair numbers within the residential area around London, and at least two of them exist in great numbers in certain populous country districts.

Contributory Mitigating Influences.

Before considering exactly how a sanitary environment has managed, quite accidentally, to separate anopheles from mankind in this country, certain other factors that must have helped to mitigate the risk from the insect as this separation progressed must be taken into account.

First there is the limited infectivity of the insect in our variable climate. Whatever may happen under conditions of temperature and humidity that can be controlled in the laboratory, it is certain that the proportion of insects that develop an infection when left exposed to natural influences after feeding on a suitable malaria patient is in this country very inconstant, and may even be as low as 3·3 per cent. of a considerable batch. It appears, indeed, that if it could be imagined desirable to attempt to make our British anopheles generally infective under the sanitary regimen of the present day, the attempt could get fairly floated only in a summer having fairly long spells of weather that is hot without also being dry. But, as any ordinary proposition, it is obvious that as the numbers of anopheles diminish with the disappearance of temporary breeding-places by drainage, this variable infectivity of the insect in a variable climate would tell in reducing malarial fever.

Then there is the protection afforded by domestic animals. Roubaud, in France, attributes the absence of malaria in parts of that country where the anopheles are abundant (*anophélisme sans paludisme*) to the increase of domestic animals, particularly cattle, and more particularly stalled cattle. He has gone so far as to assert that in some such districts the anopheles have become functionally and even structurally adapted to cattle (*zoophile*) and have developed a correlated aversion to man. There is, however, no general concord of evidence that the insect prefers the blood of cattle to that of horses, or pigs, or rabbits, or man, though there would perhaps be more general agreement that it prefers a cattle-shed or a stable even when empty to a well-constructed house even when it is inhabited.

The Two Outstanding Factors in Prevention.

From this last promontory can be seen the two outstanding items of sanitary progress that most seem to have worked together in ridding this country of malaria and preventing its reintroduction in spite of the abundance of susceptible anopheles—namely, drainage and generally improved housing. The importance of drainage in restricting breeding-places and drying the soil is too well understood to require further comment. But the equal importance of dry, light, airy houses seems to have been realised only by Dr. C. W. Daniels, Colonel S. P. James, and a few others. And yet there are some facts of common observation that suggest the influence of the house. There is the significant fact that in certain Indian cantonments—and these not notoriously malarious—there may be (or once was to be) found some one particularly malarious house having the opprobrious name of "Fever Hall." Colonel James, too, has emphasised the existence in the Medway estuary of little nests of native malaria focused in a particular street, or a particular house where the anopheles make themselves at home. Conversely, there are places not a few, in the residential area around London, where anopheles larvæ are to be found in any pond and adult anopheles in any cowshed or stable, though search for an anopheles in the excellent modern residence close by would be vain. Moreover, there is more than one salubrious spot within a few hours of London—once ague-stricken, but where ague is now a vague and almost obliterated tradition—in which in July 50 anopheles larvæ may be taken from a stream at one dip of a cup, and in October adult anopheles innumerable may be caught in a cowshed or a stable though none will be found in well-built and well-kept houses not a hundred yards distant. Why anopheles is so susceptible to the effects of a dry atmosphere is a biological question that does not seem to have been investigated; the absence (in all the British species) of the thick coat of scales possessed by other kinds of mosquitoes may have something to do with it. But there is nothing strange in its shunning a particular sort of house close to its haunts; there are several other kinds of blood-sucking flies that show the same discrimination.

Conclusion.

The conclusion of the whole matter is that it is chiefly an absence of a sanitary environment that makes anopheles dangerous, just as it is chiefly an absence of a sanitary environment that makes the generality of germ-carriers and germs dangerous. In places where the sanitary environment does not exist—e.g., most rural areas in the tropics—and in expeditionary camps, where the natural environment may have to be defied, anopheles is a danger that requires prompt and special attention. But in places like these islands, where an efficient sanitary service is maintained, anopheles is *not* a real danger to the public health, and as also it is *not*, like certain species of *Ochlerotatus* and like *Culex pipiens*, an ordinary nuisance—since it may be found, by search, in swarms where the inhabitants are quite ignorant of its existence—any deliberate attempts to exterminate the insect would truly be *ἀνωφελής*, or, rather, *ἀνωφελέστατον*, that is to say, most unprofitable; for such attempts would give endless annoyance to farmers, who have quite enough trouble to put up with as things are, and also would tend to shake public confidence in the established sanitary administration.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 1349.)

MEDICAL SERVICES IN THE FACTORY.

Evidence of Sir T. M. Legge, M.D.

(App. XLII. and Q. 13515–13726.) Sir Thomas Legge, Senior Medical Inspector of Factories, gave evidence not in an official capacity but as embodying his personal views. His principal contention was that, although the worker in the factory went to his panel doctor when he became ill, there was no provision whereby the clinical knowledge of the insurance doctor was utilised in preventive work in the factory. He showed this by a chart with arrows pointing away from the factory and the workshop indicating that the workers stream from the factory to their panel doctors when they become ill. There was no return stream from the panel into the factory to try to prevent sickness claims arising there, which must ultimately fall on the National Health Insurance Funds. The duties of the factory surgeon were merely to certify fitness or disablement. The witness was sure that there was no chance of the creation of a new whole-time service of medical men as factory surgeons in this country.

> The only way . . . . in which the services of those who have the clinical experience suitable for the medical supervision can be obtained is, I believe, by some broadening of the National Health Insurance Act, so that in industrial areas certain practitioners should be given, as their panel work, the duty of keeping the industrial workers as far as possible from succumbing to illness and so becoming a charge on the insurance funds.

The witness said that he thought that both employers and trade-unionists would welcome medical supervision in the factory by a medical man for whose services they both contributed. Sir Thomas Legge urged the importance of including within the medical curriculum the relation of occupation to health, and said that much of the sickness and incapacity among the workers was preventable.

> I do not regard industrial hygiene and industrial medicine as an entity in itself, but simply as a specialised part of general medicine and surgery, from which they cannot properly be detached. Early clinical evidence of disease predisposed to, accentuated, or produced by, industry is wanted (1) for diagnosis, (2) for prevention, and (3) for treatment.

THE MINISTRY OF HEALTH INQUIRY ROOM.

(App. XLI. and Q. 13412–13514.) The clerk in charge of the inquiry room at the Ministry of Health gave evidence with regard to the number of inquiries which he received in the course of the year. The average number of personal calls is 3000 and there is a similar number of telephone calls. Surprisingly few complaints against the medical service are received, and it has been noted that with very few exceptions those persons who speak to the detriment of the insurance medical service have never been under the treatment of a panel practitioner.

NATIONAL SAILORS' AND FIREMEN'S UNION.

(App. XLIII. and Q. 13954–14058.) Mr. T. Chambers, who is in charge of the work of the union as an approved society, said that it was a registered trade-union with a membership of 58,000. The seafarer must always be a special problem within every national industrial problem. The method of collecting contributions from seamen appears from experience to be unsatisfactory. Numbers of men lose their cards or destroy them altogether, and this results in loss of credits to the Society and loss and inconvenience to the member when he is claiming benefit. The witness made suggestions for meeting this difficulty, involving the abolition of the contribution card system. Although he said that he saw grave difficulties in the way of segregating the whole body of seamen in one approved society because of the changes in employment, he thought that if this step were taken, it was essential that the Society should be under the control of its own members—in other words, the National Sailors' and Firemen's Union was quite competent to be that Society.

As to medical benefit for seamen, the witness saw no reason for any special arrangements, and said that their members who came under the ordinary machinery of the Act never made any complaint that they experienced difficulty in getting medical attention when they needed it. The Society pays less into the general medical benefit pool in respect of its members, because it gets a rebate for the periods in which seamen are abroad. This sets funds free for other benefits, and the Society give dental treatment including a contribution of about one-half towards the cost of dentures.

LOYAL ORDER OF ANCIENT SHEPHERDS.

(App. XLIV. and Q. 14059–14250.) This is a friendly society with branches called lodges. Evidence was given by Mr. John Grieve and Mr. A. J. E. Saunders. It followed in many respects evidence given by other friendly orders, including the objection to pooling surpluses, and the favouring of a limitation of additional cash benefits. The evidence contains a suggestion that the income limit for compulsory National Health Insurance should be raised from £250 to £350, on a level with the limit in the Workmen's Compensation Act, but the witnesses were unable to say that they were aware of any real demand for this.

In view of the expectation that the Society could give dental benefit out of surplus, they suggested that priority should be given in any development to the treatment of dependants.

> We are of opinion that a first step towards the establishment of a public medical service could be made by extending medical benefit to dependants of insured persons. We believe our members would be willing to pay an increased contribution for this purpose. The average man is more concerned to know that his dependants are provided with proper medical attention than he is about himself. Since the inception of National Health Insurance, although he finds himself entitled to free medical attention for himself, he finds it more difficult to provide for his dependants owing to the increased fees now charged by the medical profession for private service.

This Society thinks that serious consideration should be given to the possibilities of administering workmen's compensation on lines similar to National Health Insurance. A suggestion in the evidence that medical umpires should be appointed to settle questions in dispute between the panel doctor and the regional medical officer gave rise to a lengthy examination of the witnesses as to the merits of such a proposal. It was suggested to them that their object was merely to relieve themselves of the responsibility of determining in the light of the medical evidence whether a member should continue to receive benefit on the ground of incapacity for work. They said that their difficulty arose from the fact that the regional medical officer was not empowered to give a decision. He too often evaded the issue or left it too vague. They agreed that if he was able to give a decision they would not need the suggested umpire.

MEDICINE AND THE LAW.

Medical Evidence in Accidental Deaths.

A correspondent asks our opinion on the following occurrences: (1) A man falls from a roof, fractures his skull, and is killed instantly. (2) A man commits suicide by a gas oven and dies. On both occasions a doctor was sent for and went, and in each case an inquest was held, but no medical evidence was called. It appears that a coroner is not obliged by law to call medical evidence in cases where apparently it can add nothing material to what is known as to the cause of death. No doubt medical men will not always believe that he has acted with discretion in having no medical evidence given. Mr. R. Henslowe Wellington, himself a medical coroner, wrote in 1906 ("The King's Coroner," vol. ii., p. 23): "It is not always necessary to have medical evidence at an inquest, so that the expense of calling it should not be incurred unless the coroner is satisfied that a skilled and scientific examination is necessary in order to determine the cause of death," and (p. 68) "The immediate cause of death may be shock, due to being knocked down or run over by a train, and the remote cause as to who if anyone was to blame for the death; or a person may have been seen to throw himself from a height, or deliberately cast himself into a river and drown." The object in calling medical witnesses in all such cases—namely, the elimination of other causes of death than the obvious one—could only be attained by post-mortem examination, and generally speaking would hardly be worth the expense. But a man might have died of heart failure before falling off a roof or before the gas in a gas oven operated sufficiently to kill him, and this would be worth finding out in the case of an accident if a question of insurance turned on it. In such a case, however, medical evidence would be called, unless there was independent evidence proving an accident. The medical man summoned to an inquest and not called is, of course, entitled to his fee. The Act says (Coroners Act, 1887, Sec. 22): "A legally qualified medical practitioner who has attended at a coroner's inquest in obedience to a summons of the coroner under this Act shall be entitled to receive such remuneration as follows—" which evidently contemplates the conditions described.

A Question of Time-limit.

An important decision affecting the time-limit within which actions can be brought against the officials of public authorities in connexion with the performance of their official duties was given in the Divisional Court in the case of Freeborn *v.* Leeming. The plaintiff, Mr. G. Freeborn, injured by a motor-car, was treated in the Kendal Workhouse Infirmary by Dr. R. Leeming, as medical officer to the guardians, from Sept. 5th to Oct. 15th, 1923, when he left by his own wish and went to his home in Lincolnshire. It was there found by other medical men that he had suffered all the time from a dislocated hip, which Dr. Leeming had failed to discover or to treat, and that it was then too late for the dislocation to be reduced. It was found by the county court judge, on Freeborn bringing an action against Dr. Leeming, that there had been negligence, and he awarded £1800 damages, holding that the action, commenced six months and ten days after the plaintiff left the defendant's care and was not barred by the Public Authorities Protection Act, 1893; the cause of action did not arise until damage resulted to the plaintiff from the negligence, and that such damage only resulted at the time when, if he had been properly treated, he would have been able to return to work. Section 1 (*a*) of the Act in question provides that an action shall not lie "unless it is commenced within six months next after the act, neglect, or default complained of, or, in case of a continuance of injury or damage, within six months next after the ceasing thereof." Mr. Justice Salter (with whom Mr. Justice Swift agreed) held that the county court judge had decided rightly that the words "a continuance of injury or damage" meant a continuance of the act which caused the damage (Carey *v.* Mayor of Bermondsey, 20 *Times* L.R. 2), but that he was wrong in holding that no damage occurred in the case of the plaintiff until within six months of the commencement of the action. It was argued that if the dislocation had been reduced the plaintiff would have had to remain in bed for several weeks, and that therefore during such a period he suffered no damage. His lordship however, held that this was not so, but that the damage began to accrue from the time when the failure to discover the dislocation took place, the result of the failure being that during the time that followed it the plaintiff was becoming worse instead of better. His lordship on these grounds gave judgment allowing the appeal, and expressing regret that he had had to come to that conclusion.

The Medical Witness's Fee.

Dr. X was recently subpœnaed to give evidence on behalf of the plaintiff in a claim for compensation after an accident. The plaintiff won his case, and Dr. X is informed by the plaintiff's lawyer that he is entitled to a fee of 1 guinea plus 5s. expenses, but, as the defendant has not yet paid costs, Dr. X has not yet come by his money. Hitherto he has always been paid 2 guineas a day for attendance at court. Should he remain unpaid, Dr. X would like to know on whom he has any legal claim, and for how much. Speaking generally, costs of witnesses are fixed by a taxing-master or by the registrar of the county court, according to prescribed scales, with certain discretion. Presumably the solicitor was right in this case in his statement of the amount due to Dr. X after taxation, and if and when the defendant pays Dr. X will receive that sum. In the absence of any agreement for remuneration beforehand, he is unlikely to obtain more unless the plaintiff chooses to pay more. Should Dr. X find himself unable to get payment in any other way, he can claim against the plaintiff, but in that case it would be prudent to ascertain first whether the plaintiff is able to pay if he has received nothing from the defendant. Certain obvious precautions should be taken by a medical man when called upon to give evidence in a court of law. When a subpœna is served on him, he should ask for "conduct money" to which he is entitled before going to court, being not obliged to obey the subpœna until he has received it. If called on in court to give evidence, he can ask to have his fee paid before being sworn, and the judge will then decide what is a proper fee in the circumstances. In most cases, even if not called, he would still be entitled to his fee. Any witness who expects a higher fee than that ordinarily allowed on "taxation between party and party" should arrange the matter clearly then and there if he wishes to avoid disappointment afterwards. Fees thus arranged between witness and client are usually higher than those allowed on taxation.

Manchester Royal Infirmary. — Sir William Cobbett has resigned the chairmanship which he has held for 21 years on account of ill-health, and Mr. R. P. Goldschmidt has been appointed to succeed him. Sir William Cobbett was knighted at the opening of the new infirmary by King Edward in 1909.

(FROM OUR OWN CORRESPONDENT.)

Food Preservatives and Food Adulteration.

IN the *Medical Practicant* Dr. Jámbor writes on this subject. He says that the necessity of preserving food in some way had been recognised since ancient times. The development of the science of chemistry had placed in the hands of the manufacturer means of preserving food hitherto unknown and means of matching foods in tints and colours. He believes that the education of the public in regard to artificial colouring of foods would be quite as effective as legislation. After August 1st the new food law requires that all food products entering Roumania artificially coloured shall bear a label with a statement to that effect. The material for colouring need not be declared, except in the one case of sulphate of copper. The chief sanitary commissioner's advice to food makers is to cease using colours, and especially if the colouring is under suspicion of any kind. Concerning antiseptics in relation to foods, he thinks the rights of the consumer are paramount. He believes that there never should be an antiseptic added to foods, except when absolutely necessary, unless the consumer orders it for himself. There is, he thinks, a legitimate use for sulphurous acid as employed in the fumigation of dried fruits, and the burning of the sulphur match in wine barrels, a method which has come down from antiquity, but when it is used, as at present, greatly to excess for preserving a poor wine and putting on the market a new wine before it is aged, such use is unwarrantable. He believes that the application of the principle of honesty would cover all the needs of a food law.

Intestinal Tuberculosis in Children.

A type of tuberculosis occurring in children of farmers is described by Dr. Popovici. It affects principally the intestinal lymph glands and, though rarely fatal, may constitute a grave illness. The children become emaciated, pale, suffer from abdominal pain and tenderness around the umbilicus, headache, insomnia, and slight rise of temperature in the evening. The cervical and submaxillary glands are frequently swollen. The disease may progress very rapidly for a time, and then take on a chronic type, which is more apt to be prolonged in the older children. After the subjective symptoms disappear, anæmia and general weakness persist for a considerable period. Dr. Popovici attributes the occurrence of the disease to the fact that there was an epidemic among the cows of the district, and although their milk was wholesome (the epidemic consisting only of the occurrence of some external manifestations) it was nevertheless of very poor quality.

Removal of Large Sharp Bodies from the Œsophagus.

In the Medical Society of Cluj Dr. Koleszár spoke about the difficulty of extracting large sharp bodies from the œsophagus. He said that external œsophagotomy is the operation usually advised for their removal. The technique of the operation is difficult and the results are inconstant. It follows from this that if careful extraction can be accomplished through the mouth the results must be better than by operation, especially if operation be in the hands of a somewhat inexperienced surgeon. Dr. Koleszár cites the history of two cases which showed him conclusively that the incision of the œsophagus for the extraction of foreign bodies, even in apparently desperate cases, might not always be necessary. The technique practised is as follows. The œsophagus is exposed by the usual incision on the left side of the neck. The incision made is at least 0 cm. in length, or longer if necessary, to give the operator a full view of the œsophagus. Instead of opening the organ he practises the following method (Kramer's method). While lifting the patient's head forward and pulling the larynx up with the left hand, he endeavours with two fingers of the right hand in the wound, under the control of the X ray screen, to push the foreign body into a different position in the œsophagus. After some effort in each case this manipulation proved successful, and he was able to pass the usual slender œsophageal forceps through the mouth and remove the body which previously had resisted all forms of intrabuccal manipulation. He considers that inasmuch as the statistics show that œsophagotomy is connected with a very high mortality-rate, any method which enables the operator to remove the body without subjecting the patient to such very high risk must be of great value.

Inflammatory Process of the Sigmoid Flexure.

Dr. Dumitrescu-Mante, lecturer to the University of Bucharest, read a paper in the Bucharest Medical Society on the above subject. He drew attention to the frequency of benign inflammatory processes in and about the sigmoid flexure. As separate and distinct affections these have not received proper study and have frequently been overlooked or else wrongly diagnosed as cancer. They may be acute or chronic and are frequently followed by strictures of a moderate grade. Although extremely troublesome, they are generally amenable to treatment without operation. The use of the barium enema and the sigmoidoscope mark a very great advance in diagnosis, since a great portion of the sigmoid flexure may now be inspected directly by the latter method. Even exploratory laparotomy is often less successful than direct inspection, since the interior of the gut often gives more information than the exterior. It may well happen that the walls of the flexure are thickened to such an extent by simple chronic inflammation that the operator may have considerable doubt as to the nature of the condition. The most common symptoms are pain, irregularities of defæcation, and tenderness. The loop may be palpated as a thickened mass or as a distinct tumour. An acute sigmoiditis may be the result of simple chronic constipation. Fever and general malaise are common here, and occasionally attacks of obstruction, which yield, however, to castor oil and enemata. A mild general infection is probably set up from an acute ulceration or a diverticulum in which the fæces stagnate, with secondary irritation of the peritoneum. Inspection will generally show an œdematous and hyperæmic mucous membrane. If the intestines are distended with air, the sigmoid will not balloon out. In the chronic cases the patients are frequently so cachectic that the diagnosis of carcinoma seems probable. The mucous membranes are also very vascular here, but areas of pigmentation from former hæmorrhages are very common. The stools frequently contain mucus and blood. Follicular inflammation is rare, but may also readily be diagnosed with the proctoscope. The treatment of all these conditions calls for regulation of food and stools, mild astringent irrigations, and tonic drugs.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Annual Meeting of the A.M.A.

ONE of the more important incidents, and certainly the most exciting, of the recent meeting of the American Medical Association at Atlantic City was the discussion of a quarrel now going on between the Judicial Council of the Association and the Life Extension Institute. The latter organisation was incorporated, largely through the efforts of its President, Mr. Harold A. Ley, in 1913. The object of the institute was to encourage periodical medical examinations as a means to study early symptoms, to secure early treatment, and so save life. The Institute, though for several years run at a financial loss, has been successful in promoting the idea of medical examinations, and according to the report of the Metropolitan Life Insurance Company, whose policy-holders are entitled to free examination by an arrangement with the Institute, it has been notably successful in reducing the mortality-rate among its clients. In the year 1923 a dividend of 3¼ per cent. was paid on the preferred stock. Apparently it is only within the last two years that the officers of the American Medical Association have taken umbrage at this campaign. At the last annual meeting in Chicago the Judicial Council issued a report on the practises of certain "commercial organisations." The Life Extension Institute believes that it recognises references to its own procedure in this report and has printed a refutation in parallel columns of the statements in this report which it says are untrue. This year the Judicial Council is called on by a resolution in the House of Delegates—a resolution which warmly resents the imputation of dishonesty made by the Life Extension Institute—to present information or proof that will vindicate its position, "so that suitable action may be taken by this House."

On the motion of the Reference Committee on Reports of Officers, the following resolutions were carried :—

Resolved.—That it is the sense of this House of Delegates that periodic health examinations should be conducted by medical men and neither dominated by, nor controlled by, lay organisations, for the reason that the relation between the patient and the physician is an individual matter and anything that disturbs such relationship is detrimental to the best interests of the patient ; and it is further

Resolved.—That it is the sense of the House of Delegates that every Fellow and Member of the American Medical Association should live up to the spirit and letter of this resolution.

If these resolutions should be carried out it is obvious that the Life Extension Institute would disappear. Actually two members of their Hygiene Reference Board have resigned, but the remainder, including some of the most prominent members of the American medical profession, seem to be standing behind the organisation. The indications are that the Institute will survive, and continue to work both for private applicants and for the life insurance companies.

Medical Education.

The report of the Council on Medical Education and Hospitals includes some interesting figures. In 1900 there were 160 medical schools in the United States—more than half the world supply. In all but about 30 the entrance requirements were absent or nominal ; many schools had no laboratories and were not even attached to hospitals. Now, of the 70 medical schools teaching clinical subjects 34 have their own teaching hospitals and 30 have access to other hospitals by which satisfactory clinics are being regularly held. Seventy-five colleges, or 93·7 per cent., have entrance qualifications "similar to those of the rest of the world." The expense of maintaining these colleges has naturally increased. Students' fees have been raised, but even now cover only one-quarter of the increased expense. The number of approved post-graduate schools has increased from 20 to 50 in the last ten years.

WOMEN'S MEMORIAL IN YORK MINSTER: UNVEILING CEREMONY.

THE Five Sisters window in York Minster, in memory of women who gave their lives for their country in the war, was unveiled on June 24th. During the war bombs fell so near the Minster that it was decided to remove and bury the windows. It was then discovered that the glass was perishing, and the Dean sent out an urgent appeal for financial assistance to save it. So far no memorial had been erected to all the women who gave their lives in the war, and the idea arose that to save the Five Sisters window, which has always been associated with women, would be a suitable memorial. The subscription list was headed by Princess Mary with £50, and followed up by varying sums from all classes ; one old age pensioner gave her weekly 10s. Within nine weeks over £3000 had been received, so that it was possible to erect in addition an oak screen with a roll of honour containing the names of the women commemorated, in such a position that the light shining through the window falls on the names on the screen.

The window occupies the entire end of the North Transept. It is formed of five lancet-shaped lights with a pointed panel above. Each light contains 12 panels of glass, each about 5 ft. broad by 4 ft. high. The ground-work of the whole is of whitish-green glass on which is painted in brown enamel a continuous pattern interrupted by insertions of coloured glass of different colours in geometrical designs. This style of glass is known as grisaille and the Five Sisters window contains the greatest quantity of it in existence at the present time. The name has been derived from the story, which may be true or only a legend, that five sisters who lived near York Minster embroidered tapestries of such beautiful design that the maker of the window used the designs for his glass. The window dates from the thirteenth century, but until the unveiling on June 24th, the glass has been so altered that it has not been seen in its true colours except when it was new. The lead used for the restoration was given by the owner of the old Abbey of Rievaulx in Yorkshire, and by a happy coincidence is also thirteenth century lead.

The screen has been placed in the St. Nicholas Chapel near to the window. It is made of oak which belonged to the Minster. The upper part of the screen is perforate, the lower part consists of 12 panels on which the names of the 1400 women commemorated are inscribed. Each panel is covered by a door which has to be opened before the names are revealed. Panel 6 contains the names of the women *doctors, Scottish Women's Hospitals, Endell-street Military Hospital, and the auxiliary hospitals.* The names of the medical women on the panel are : Dr. Laura Foster, Dr. Elsie Impey, Dr. Sybil Leonie Lewis, Dr. Isobel Addu Tate, Dr. Marion Wilson, Dr. Elsie Maud Inglis (founder of Scottish Women's Hospitals), Dr. Louisa Woodcock.

On the outside of the door of the panel is the emblem of the medical profession, the rough stock with the twisted serpent.

Deputations from all branches of women's war service attended the ceremony, including the following medical women : Miss Frances Ivens, representing the Medical Women's Federation ; Dr. A. C. Scott, Delhi ; Dr. M. G. Brodie, Durham ; Dr. I. J. Fowler, Halifax ; Dr. M. Keyes, Dr. K. E. H. Rutherford, and Dr. L. Veale, Harrogate ; Dr. D. P. Priestley, Dr. A. W. Somerville, and Dr. C. Stewart, Leeds ; Dr. R. Nicholson, Liverpool ; Dr. J. H. Turnbull (Ministry of Health), London ; Dr. E. Stone-Milestone, Sheffield ; Dr. H. A. Wilson, Wakefield ; Dr. J. S. Baugh, Dr. E. M. Creak, Dr. L. Fraser, Dr. H. Gibson, Dr. N. Kemp, Dr. A. Maclaren, Dr. L. Mill, Dr. P. M. Platt, Dr. Ross, Dr. Shirlaw, Dr. Urwick, and Dr. E. M. Walker, York.

At the same time as the ceremonial was taking place in York, similar services were being held in Canada, South Africa, South and West Australia, Tasmania, and New Zealand.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The thirty-third meeting of the Commission was held in Edinburgh on June 23rd, Prof. Alexander Gray in the chair. Evidence on the question of the supply of medicines and drugs in Scotland under the Insurance Scheme was given by Mr. Rutherford Hill on behalf of the General Council of Panel Chemists of Scotland. The National Farmers Union of Scotland, represented by Mr. J. C. Henderson, submitted evidence as to the position of agricultural societies in the scheme and the need for reducing the rate of contribution for agricultural workers in view of their higher standard of health. Dr. A. Asher, of Thurso, gave evidence on various aspects of the medical service under the Act in rural areas. —The thirty-fourth meeting was held at the Home Office, Whitehall, on June 25th. Lord Lawrence of Kingsgate in the chair. Evidence was submitted on behalf of the Queen Victoria's Jubilee Institute for Nurses by Miss Peterkin, Mrs. Bruce Richmond, and Major H. F. Cadell : the College of Nursing by Miss Watt, Miss Viney, and Miss Bremner ; the Incorporated Midwives Institute by Miss Doubleday and Miss Gilligan ; and the Scottish Midwives Association by Miss Barker. Thereafter Mr. J. L. Cohen, of the Department of Economics, Cambridge University, gave evidence on the structure of the Insurance Scheme and the need for fundamental alterations in certain directions.

The Institute, though for several years run at a financial loss, has been successful in promoting the idea of medical examinations, and according to the report of the Metropolitan Life Insurance Company, whose policy-holders are entitled to free examination by an arrangement with the Institute, it has been notably successful in reducing the mortality-rate among its clients. In the year 1023 a dividend of 3¼ per cent. was paid on the preferred stock. Apparently it is only within the last two years that the officers of the American Medical Association have taken umbrage at this campaign. At the last annual meeting in Chicago the Judicial Council issued a report on the practises of certain "commercial organisations." The Life Extension Institute believes that it recognises references to its own procedure in this report and has printed a refutation in parallel columns of the statements in this report which it says are untrue. This year the Judicial Council is called on by a resolution in the House of Delegates—a resolution which warmly resents the imputation of dishonesty made by the Life Extension Institute—to present information or proof that will vindicate its position, "so that suitable action may be taken by this House."

On the motion of the Reference Committee on Reports of Officers, the following resolutions were carried:—

Resolved.—That it is the sense of this House of Delegates that periodic health examinations should be conducted by medical men and neither dominated by, nor controlled by, lay organisations, for the reason that the relation between the patient and the physician is an individual matter and anything that disturbs such relationship is detrimental to the best interests of the patient; and it is further

Resolved.—That it is the sense of the House of Delegates that every Fellow and Member of the American Medical Association should live up to the spirit and letter of this resolution.

If these resolutions should be carried out it is obvious that the Life Extension Institute would disappear. Actually two members of their Hygiene Reference Board have resigned, but the remainder, including some of the most prominent members of the American medical profession, seem to be standing behind the organisation. The indications are that the Institute will survive, and continue to work both for private applicants and for the life insurance companies.

Medical Education.

The report of the Council on Medical Education and Hospitals includes some interesting figures. In 1000 there were 160 medical schools in the United States—more than half the world supply. In all but about 30 the entrance requirements were absent or nominal; many schools had no laboratories and were not even attached to hospitals. Now, of the 70 medical schools teaching clinical subjects 31 have their own teaching hospitals and 30 have access to other hospitals by which satisfactory clinics are being regularly held. Seventy-five colleges, or 03·7 per cent., have entrance qualifications "similar to those of the rest of the world." The expense of maintaining these colleges has naturally increased. Students' fees have been raised, but even now cover only one-quarter of the increased expense. The number of approved post-graduate schools has increased from 20 to 50 in the last ten years.

WOMEN'S MEMORIAL IN YORK MINSTER: UNVEILING CEREMONY.

THE Five Sisters window in York Minster, in memory of women who gave their lives for their country in the war, was unveiled on June 24th. During the war bombs fell so near the Minster that it was decided to remove and bury the windows. It was then discovered that the glass was perishing, and the Dean sent out an urgent appeal for financial assistance to save it. So far no memorial had been erected to all the women who gave their lives in the war, and the idea arose that to save the Five Sisters window, which has always been associated with women, would be a suitable memorial. The subscription list was headed by Princess Mary with £50, and followed up by varying sums from all classes; one old age pensioner gave her weekly 10s. Within nine weeks over £3000 had been received, so that it was possible to erect in addition an oak screen with a roll of honour containing the names of the women commemorated, in such a position that the light shining through the window falls on the names on the screen.

The window occupies the entire end of the North Transept. It is formed of five lancet-shaped lights with a pointed panel above. Each light contains 12 panels of glass, each about 5 ft. broad by 4 ft. high. The ground-work of the whole is of whitish-green glass on which is painted in brown enamel a continuous pattern interrupted by insertions of coloured glass of different colours in geometrical designs. This style of glass is known as grisaille and the Five Sisters window contains the greatest quantity of it in existence at the present time. The name has been derived from the story, which may be true or only a legend, that five sisters who lived near York Minster embroidered tapestries of such beautiful design that the maker of the window used the designs for his glass. The window dates from the thirteenth century, but until the unveiling on June 21th, the glass has been so altered that it has not been seen in its true colours except when it was new. The lead used for the restoration was given by the owner of the old Abbey of Rievaulx in Yorkshire, and by a happy coincidence is also thirteenth century lead.

The screen has been placed in the St. Nicholas Chapel near to the window. It is made of oak which belonged to the Minster. The upper part of the screen is perforate, the lower part consists of 12 panels on which the names of the 1400 women commemorated are inscribed. Each panel is covered by a door which has to be opened before the names are revealed. Panel 6 contains the names of the women doctors, Scottish Women's Hospitals, Endell-street Military Hospital, and the auxiliary hospitals. The names of the medical women on the panel are: Dr. Laura Foster, Dr. Elsie Impey, Dr. Sybil Leonie Lewis, Dr. Isobel Addu Tate, Dr. Marion Wilson, Dr. Elsie Maud Inglis (founder of Scottish Women's Hospitals), Dr. Louisa Woodcock.

On the outside of the door of the panel is the emblem of the medical profession, the rough stock with the twisted serpent.

Deputations from all branches of women's war service attended the ceremony, including the following medical women: Miss Frances Ivens, representing the Medical Women's Federation; Dr. A. C. Scott, Delhi; Dr. M. G. Brodie, Durham; Dr. I. J. Fowler, Halifax; Dr. M. Keyes, Dr. K. E. H. Rutherford, and Dr. L. Veale, Harrogate; Dr. D. P. Priestley, Dr. A. W. Somerville, and Dr. C. Stewart, Leeds; Dr. R. Nicholson, Liverpool; Dr. J. H. Turnbull (Ministry of Health), London; Dr. E. Stone-Milestone, Sheffield; Dr. H. A. Wilson, Wakefield; Dr. J. S. Baugh, Dr. E. M. Creak, Dr. L. Fraser, Dr. H. Gibson, Dr. N. Kemp, Dr. A. Maclaren, Dr. L. Mill. Dr. P. M. Platt, Dr. Ross, Dr. Shirlaw, Dr. Urwick, and Dr. E. M. Walker, York.

At the same time as the ceremonial was taking place in York, similar services were being held in Canada, South Africa, South and West Australia, Tasmania, and New Zealand.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The thirty-third meeting of the Commission was held in Edinburgh on June 23rd, Prof. Alexander Gray in the chair. Evidence on the question of the supply of medicines and drugs in Scotland under the Insurance Scheme was given by Mr. Rutherford Hill on behalf of the General Council of Panel Chemists of Scotland. The National Farmers Union of Scotland, represented by Mr. J. O. Henderson, submitted evidence as to the position of agricultural societies in the scheme and the need for reducing the rate of contribution for agricultural workers in view of their higher standard of health. Dr. A. Asher, of Thurso, gave evidence on various aspects of the medical service under the Act in rural areas. —The thirty-fourth meeting was held at the Home Office, Whitehall, on June 25th, Lord Lawrence of Kingsgate in the chair. Evidence was submitted on behalf of the Queen Victoria's Jubilee Institute for Nurses by Miss Peterkin, Mrs. Bruce Richmond, and Major H. F. Cadell; the College of Nursing by Miss Watt, Miss Viney, and Miss Bremner; the Incorporated Midwives Institute by Miss Doubleday and Miss Gilligan; and the Scottish Midwives Association by Miss Barker. Thereafter Mr. J. L. Cohen, of the Department of Economics, Cambridge University, gave evidence on the structure of the Insurance Scheme and the need for fundamental alterations in certain directions.

Public Health Services.

THE HEALTH OF LONDON IN 1924.

Sir William Hamer, medical officer of health and school medical officer to the London County Council, estimates the mid-year civilian population of the County of London in 1924 as 4,576,505, and there were in addition 9495 non-civilian residents. The marriage-rate was 17·2, about the same as in the previous year. The birth-rate was 18·6, as compared with 20·1 in 1923 and 20·9 in 1922. A diagram shows that while the birth-rate has been halved since 1870, the marriage-rate has remained practically stationary. Thus the birth-rate for 1871–75 was 35·3 and the rate for 1921–25 was 20·0. During the same quinquennia the marriage-rates were 19·6 and 18·0 respectively. The regularity of the diagram is broken by the increase in the marriage-rate caused by the war marriages and a temporary subsequent increase in the birth-rate.

The *death-rate* was 12·2, as compared with 11·4 in the previous year. The increase is chiefly due to the increased fatality of measles among children under 5 years of age, and the greater number of deaths at ages over 45 due to the greater prevalence of influenza. Encephalitis lethargica caused a considerable number of deaths. The cancer and phthisis deaths increased somewhat, while a decrease occurred in the mortality from diarrhœa and enteritis. A table is given showing the death-rates for the county and the 29 metropolitan boroughs. The infant mortality for London was 69·0; the typhoid fever-rate 0·01; the phthisis-rate 0·98; and the cancer-rate 1·42. Turning to the metropolitan boroughs and excluding the small resident population of the City (13,621), the highest birth-rates were found in Shoreditch (25·0) and Bermondsey (24·3); the lowest in Westminster (11·2), Holborn (13·4), and Hampstead (13·5). The lowest death-rates from all causes occurred in Lewisham (10·4), Woolwich (11·0), Wandsworth (11·1) and Fulham (11·1); while the highest were 14·3 in Finsbury and 14·1 in Southwark. The best infant mortality-rates were in Lewisham (48), Hampstead (56), Stoke Newington (56), Wandsworth (57), and Hackney (59). Bethnal Green had a typhoid-rate of 0·10, the only other boroughs which reached 0·03 being Hampstead and Deptford. The highest rates from phthisis were 1·4 in Southwark, 1·24 in Chelsea, 1·23 in Finsbury, and 1·22 in Woolwich; the lowest being 0·66 in Hampstead, 0·68 in Kensington, 0·7 in Stoke Newington, 0·72 in Lewisham, and 0·73 in Wandsworth. The highest cancer-rates were 1·83 in St. Marylebone and 1·72 in Hampstead; the lowest being 1·0 in Paddington and 1·02 in Bethnal Green. Deaths caused by vehicles and horses show an increase. In London there were 593, 166 being children under 15. Taking for comparison Great Britain as a whole, motor vehicles caused more than eight deaths per day in 1924, being an increase of 24 per cent. on 1923. In the United States during 1924 motor vehicles caused 52 deaths per day, being an increase of 4 per cent. on the 1923 figure.

The condition of Europe as regards *small-pox* was more favourable than recently, but the presence in the North and Midlands of a mild form of small-pox was a continual menace to London. Prompt and correct diagnosis and efficient administration, in the absence of full protection by vaccination and revaccination, are the chief measures by which London is protected. The County Council places at the disposal of medical officers of health and medical practitioners in London and certain neighbouring areas the services of its expert medical staff for assistance in diagnosis, and coöperates with all the sanitary and port authorities in the country. A history is given of the five cases of small-pox which occurred in London during 1924 and of the four persons, who sojourned in London, en route for other destinations, and were attacked by small-pox after leaving.

In London the death-rate from *diphtheria* and *scarlet fever* was practically stationary, while in New York diphtheria showed a small increase on the comparatively low rate for 1923. Sir William Hamer has previously shown that from 1859 to the end of the nineteenth century New York had a far heavier death-rate from diphtheria than England and Wales or London, and suggested that in New York City, before it was extended, diphtheria deaths frequently included scarlet fever and other forms of throat inflammation. This view is confirmed by a diagram showing the similar behaviour of diphtheria and scarlet fever mortality, when taken together, in New York and London from 1866 to 1924. Except for the period from 1870 to 1890 the mortality curve of the two cities from these two diseases is very much alike. Another interesting diagram dealing with the diphtheria record of 24 towns in this country shows the remarkable way in which diphtheria gradually spreads from one part of this country to another. "The impression left on the mind," says Sir William Hamer, "is one of an eminently infectious disease, but of one which spreads quite slowly from one area, town, or country to another, so that whereas in a period of four, five, or more years a continent or large area may suffer severely, the extent to which portions of such continent or other large area are involved varies greatly within the series of years under review." The outstanding fact is that widespread epidemics of throat disease have shown a tendency to occur in Europe and America at recurring intervals of some 20 to 30 years. It has also been noted that epidemics of influenza influence throat epidemics.

There were six cases of human *anthrax* reported during the year, one of which proved fatal. In four cases the employment of the patients involved handling imported hides; the fifth case was a girl of 10, whose father and brothers handled hides, and the sixth case was thought to have contracted it from a shaving-brush. Notified cases of *encephalitis lethargica* numbered 605. In 64 cases the diagnosis was revised, reducing the number to 541, with 122 deaths and a case fatality of 45·0 per cent. The prevalence of the disease was most marked in April and May. Sir William Hamer considers in detail the relationship between influenza and cerebro-spinal fever, poliomyelitis and polio-encephalitis, and encephalitis lethargica. The pandemic of influenza in 1918 was preceded by unusual prevalence of cerebro-spinal fever in 1915, and of poliomyelitis in 1916, and was succeeded by the encephalitis prevalences of 1921 and 1924. After discussing the matter at length, Sir William Hamer inclines "to accept the conclusion that the whole group of epidemic diseases primarily affecting the nervous system exhibits a close family likeness (epidemiologically speaking) and a very close relationship, too, with influenza."

After full consideration of the circumstances of the Bethnal Green prevalence of *typhoid fever* during 1924, Sir William Hamer thinks that the various facts elucidated point very suggestively to small plaice or dabs as the source of infection. "Prior to 1906 these fish, he says, were widely implicated on several occasions in London. This cause, however, ceased to operate in 1909 and (with an exception in 1911) remained conspicuous by absence until after the war. It is suggested that this source of danger, judging from London experiences in the autumns of 1923 and 1924, has recurred and that a close watch should be kept.

The need for removing conditions likely to cause patients to discontinue attendance at the *venereal disease clinics* is receiving careful attention, and the fact that during 1924 the ratio of attendances to venereal cases was in the proportion of 32 to each new case is valuable evidence of improvement in methods. Such a ratio has never been greater in countries where compulsory notification has been adopted.

The Public Health Committee is investigating the possibility of arranging for a large scale test of artificial light treatment under satisfactory conditions, in association with the Education Committee and in consultation with the Ministry of Health.

School Report.

The school report contains several cheering items. For example, the children classed as below the normal in nutrition numbered 6·2 per cent., as compared with 12·8 per cent. in the year before the war. Had it not been for the vigilance of the head teachers and the school care committee in bringing into timely operation the remedial agencies, which now exist to an extent undreamt of before the war, the prolonged period of unemployment must have produced disastrous results. Again the percentage of verminous conditions found was 16·1, the lowest yet recorded, and the number of cases of scabies treated was the lowest since 1914. The devoted work of the school nursing staff, supported by the influence of the head teachers, has "literally revolutionised the standard of personal cleanliness attained by elementary school-children in London." In 1923 the proportion of older girls with hair completely free from vermin reached 80 per cent. for the first time. In 1924 the figure was 82·5 per cent. In 1902, when the work began, "the conditions found were indescribable," but in 1913 the free-from-vermin figure had only reached 67·2 for the older girls. Conditions as regards teeth have improved greatly, but "there still remains a very serious amount of dental decay."

Visual acuity also shows improvement. In 1913 the percentage of children aged 12 with vision 6/12 or worse was boys 22·7, girls 25·7. For 1924 the figures were boys 20·1, girls 21·6. The difference between the two sexes, which Sir William Hamer attributes to the employment of girls in indoor occupations involving eyestrain, has thus been reduced from 3 to 1·5. The Jewish schools show an abnormally heavy incidence of visual defects, and in this case the boys come out worse than the girls, and this is attributed to the effect upon the boys of long hours spent in the evenings studying Hebrew.

There were a number of *special inquiries* made during 1924. One was made at the request of Sir George Newman with regard to the signs and effects of congenital syphilis. Dr. Nairn Dobbie investigated the past history of children with heart disease in order to ascertain the early signs of cardiac implication. Dr. Elizabeth M. McVail followed up the school history of premature infants, and found that if such babies survived to school age there was no very great deviation from the normal in general physique. Dr. Percy Stocks made investigations on blood pressure, and found that up to 11 years the mean systolic pressure rises uniformly, that during adolescence the gradient is temporarily increased and reaches a uniform level at the eighteenth year, showing no further rise up to the age of 35 or 40; and that the diastolic pressure rises uniformly until adolescence, more slowly up to 17, then rapidly to 20, after which it falls slightly to 35. Dr. Stocks's investigations do not support the commonly accepted rule that blood pressure rises uniformly throughout life.

An inquiry with regard to the results of operations on tonsils and adenoids supports the view that complete removal of the tonsillar tissue is desirable. The result of the first and second reinspections of children found with defects showed that 75·5 per cent. of such children had been satisfactorily treated. Dental cases present the greatest difficulty, and apart from dental cases 82 per cent. of the ailments were remedied. Convalescent camp schools and arrangements for sending debilitated children to convalescent homes for short periods did good work. The camp school at Bushey Park dealt with 16,200 boys between June, 1919, and December, 1924. It is hoped shortly to establish new open-air schools on Brixton Hill and near Ken Wood. Open-air classes were held in connexion with 95 ordinary elementary schools as compared with 80 in 1923. Attention to physical education is "decidedly on the up grade." Over 11,000 girls were taught to swim during the year and 2875 life-saving certificates were gained. Net-ball is the chief organised game played by the girls. Health classes with special exercises for round shoulders, lateral curvature, lordosis, and flat-foot give good results, and were in operation at 41 schools at the end of the year. Dr. F. C. Shrubsall has specially investigated the effects of encephalitis lethargica and also supplies a report on the mental examination of delinquent children, which includes inquiries made with regard to this subject in the Canadian provinces and the Northern United States.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 20th, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 80; scarlet fever, 1310; diphtheria, 830; enteric fever, 58; pneumonia, 821; puerperal fever, 41; cerebro-spinal fever, 0; acute poliomyelitis, 3; acute polio-encephalitis, 1; encephalitis lethargica, 61; dysentery, 3; ophthalmia neonatorum, 101. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 62 from measles, 12 from scarlet fever, 62 from whooping-cough, 21 from diphtheria, and 32 from influenza. In London itself the deaths from influenza numbered 8, from whooping-cough 11, and from diphtheria 1.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. H. Lightfoot is placed on the Retd. List with the rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Capt. J. A. Cowan retires, receiving a gratuity.

TERRITORIAL ARMY.

Lt.-Col. W. Bowater to be Bt.-Col.

Maj. H. F. Humphreys to be Lt.-Col. and to comd. the 143rd (South Midland) Field Ambulance, vice Bt.-Col. W. Bowater.

Capt. F. M. Halley is restd. to the estabt.

Lt.-Col. (Brevet Col.) D. J. Graham is retired on completion of tenure of comd. and retains his rank.

Maj. D. M. C. Church (I.M.S. r.t.) to be Maj.

Capt. R. F. Linton resigns his commn. and retains the rank of Capt.

Capt. G. S. Lewis (late R.A.M.C., S.R.) to be Capt.

A. O. Bekenn and G. W. Robinson to be Lts.

Supernumerary for Service with O.T.C.—Capt. R. B. Green (late R.A.M.C., S.R.) to be Capt., and J. Whillis to be Lt., both for service with the medical unit, Durham University, O.T.C.

INDIA AND THE INDIAN MEDICAL SERVICE.

Lt. C. R. Henderson to be Capt.

The King has approved the retirement of Col. P. Dee and Lt.-Cols. R. Bryson (on account of ill-health) and A. M. Fleming.

Aziz Khan Mahomed Khan and Ganeshrao Venkatrao Golforkeri to be Temp. Lts.

Capt. J. M. R. Hennessy has been succeeded as Superintendent of the Borstal Institution at Lahore by Capt. N. Briggs; Maj. Thomas acts as Civil Surgeon, Poona, and Maj. B. F. Eminson acts as Civil Surgeon, Karachi. Maj. W. A. Mearns, Officiating Director of Public Health, United Provinces, has been appointed a member of the State Board of Medical Examinations, United Provinces, vice Lt.-Col. C. L. Dunn, resigned. Rai Bahadur Dr. D. D. Pandya, Assistant Director of Public Health, in charge Provincial Hygiene Institute, Lucknow, is continued in his appointment as a member of the State Board of Medical Examinations. Lt.-Col. W. D. Ritchie has been placed on special duty in Assam; Lt.-Col. G. Tate has been appointed Professor of Midwifery, King Edward Medical College, Lahore; and Mr. H. A. Taylor acts as Lecturer on Dental Surgery, Medical College, Calcutta, vice Mr. J. R. Gill.

Leave has been granted to the following officers: Lt.-Col. G. W. Maconachie, Superintendent of Prisons, Madras; Col. Hakle, Inspector-General of Civil Hospitals; Maj.

St. J. E. Handricks, civil surgeon and superintendent, District Jail, Bhandara; Maj.-Gen. Robinson, Director of Medical Services in India; Lt.-Col. Mackie, director, Bombay Bacteriological Laboratory; Maj. H. W. Acton, professor of pathology and bacteriology, School of Tropical Medicine and Hygiene, Calcutta; Capts. W. A. C. Netscher, medical officer, Eastern Bengal Railway, Kanchrapara; R. E. Murray, civil surgeon, Shahpur; Lt.-Col. Murphy, director of public health, Bombay; Lt.-Col. Davenport Jones, civil surgeon, Karachi; and Lt.-Col. Steel, civil surgeon, Poona.

DEATHS IN THE SERVICES.

Major-General Sir Henry Neville Thompson, K.C.M.G., C.B., D.S.O., late R.A.M.C., died on June 21st at Osborne aged 64. The son of the Rev. M. N. Thompson, rector of Clonmany, Donegal, he graduated in arts and medicine at Trinity College, Dublin, in 1883, entered the Army Medical Service in the following year, and reached the rank of surgeon-major in 1896. In 1898 he became major, R.A.M.C., lieutenant-colonel in 1904, and colonel in 1913. He served in the Nile Expedition of 1898 (medal and Khedive's medal); in the South African War, 1900–02 (mentioned in despatches, Queen's medal with five clasps, and the King's medal with two clasps, and D.S.O.). In the late war he was A.D.M.S., 2nd and 48th Divisions; D.D.M.S., VI. Corps; and D.M.S., First Army and British Army of the Rhine (mentioned in despatches seven times, and received the K.C.M.G. and C.B.). Additional honours included the decoration of the French Croix de Guerre and the American Distinguished Service Medal. He was also a Grand Officer of the Portuguese Order of St. Aviz, and held the Coronation and Delhi Durbar Medals and the King George Coronation Medal.

Correspondence.

"Audi alteram partem."

THE PROBLEM OF MALIGNANCY.

To the Editor of THE LANCET.

SIR,—Dr. A. E. Barclay's important suggestion regarding what he calls the existence of an *x* factor *in malignant disease* is of deep interest to us as we have been working for some years on this matter. Our results up to date are embodied in a recently published book.[1] It will be sufficient here to say that we believe—on what we think to be strong evidence—*that chronic intestinal infections and consequent* toxæmia from organisms of the non-lactose-fermenting type play a most significant part in the causation of cancer. We do not doubt there are other factors—diet, for example, influences these infections in a very marked manner, but toxæmias are of primary importance; correspondingly vaccines given at suitable intervals (long pauses being needed between doses) bring about marked effect in a large percentage of cases of malignant disease.

We are, Sir, yours faithfully,
EDWARD BACH.
CHARLES E. WHEELER.

June 26th, 1925.

To the Editor of THE LANCET.

SIR,—Dr. A. C. Jordan, in his kindly comment on my paper, is apparently in entire agreement with me, but would have me go further. The unknown *x* that I postulate he would have me name as "the toxæmia of stasis." This, however, is going a great deal further than my own observations would in any sense justify. X may possibly be a toxæmia, but if it is intestinal in origin, surely the removal of the faulty intestine, together with the *complete* removal of the growth, must inevitably cure the patient. So far as I am aware, there is no evidence pointing in this direction.

To attribute all and every disease to intestinal stasis and to label as "stasis" conditions in the bowels which are compatible with healthy longevity, is, to my mind, unscientific. Because they see what appears to be delay, *according to their ideas as to* what should happen, the stasis school would have us at once label this supposedly pathological delay as the cause of all our ills, whether it be cancer or bad teeth. Surely it is more likely that our structure is so ordered as to tolerate these terrible "*cesspool*" *conditions*, and that they may actually serve a useful function in the economics of life. The human frame is not made to standard, and what is one man's meat is another man's poison. So also what is stasis in one man is normal function in another. Where one man suffers from depression and headaches, and is thoroughly tired of the world if he does not have a daily evacuation, another suffers from other ills if he attempts to worry his intestines into a daily habit when his natural cycle would be an evacuation every two or perhaps three days. To see robust health and the apple face of perfect health in a woman whose habit is, and always has been, a motion once every three weeks or month should surely cause the most ardent stasis enthusiasts to call a halt.

What we need is some idea as to the possible normal variations as regards the passage of the intestinal contents. *So far neither Dr. Jordan nor any of the* "stasis school" have convinced me of the soundness of their premises, and I am a long way from identifying my hypothetical *x*, the underlying cause of cancerous growth, with the much abused "toxæmia of stasis."—I am, Sir, yours faithfully,

Manchester, June 26th, 1925. A. E. BARCLAY.

THE TREATMENT OF PERFORATED GASTRIC AND DUODENAL ULCER.

To the Editor of THE LANCET.

SIR,—Statements have been recently made that the operation for closure of a perforation effects permanent cure of the ulcer. My personal experience does not endorse this teaching. I have seen cases in which the symptoms of ulceration afterwards became as accentuated as before, and in which posterior gastro-jejunostomy without loop and without clamps followed by rest cured the patients. And during the 28 years which I have exclusively practised this method (with catgut suture of mucous coat and silk of serous) I have not seen a case of peptic ulcer follow.

My plan in cases of acute perforation is to open the abdomen as quickly as possible, *involute* the opening by interrupted silk Lembert sutures, and fix a patch of omentum over same. Having completed the toilet, the parietal wound is united by interrupted through-and-through double silkworm-gut sutures, leaving space *at upper angle for passage* of a wisp of silkworm-gut. This drain is not removed before the fifth day. The patient is then kept at rest in bed for one month on milk with the addition of glucose, whisky, or brandy to taste. After a few days' *trial of additions, preference* is generally expressed for the milk which is always diluted with citrate or other water. Posterior gastro-jejunostomy is then performed and similar rest and diet continued for another month, at the end of which a month of milk pap, glucose, and egg nog dietary begins.

Before discharge the patient's menu for the ensuing year is mapped out, with rider to cleanse his teeth morning and evening with a soft brush and soda or plain water, to eat meat cooked to a turn, to eschew bread and other carbohydrates in quantity, to follow the good example of all reasonable animals by resting for at least half an hour after the midday meal, to limit fruit-eating to early breakfast, and to take at lunch and dinner his coefficient of whatever alcoholic beverage suits him best. To which is added: avoid alcohol between meals, *do not smoke* before lunch, and do not be tempted to imbibe milk or tea with a meat meal.

If some such plan of post-operative rest and dietary were generally adopted we should hear more of the virtue of gastro-jejunostomy and less about that of gastrectomy. The cells have got to do the healing, and given the general feeble power of resistance which exists in everyone who develops a chronic ulcer of stomach, there is no reason to assume that the chances of cure will be enhanced by the substitution of a large acute wound for a small chronic one. The employment of the cautery for removal of benign ulcers of stomach is not in harmony with the natural laws which favour prompt restitution of normal tissue.

---

[1] Chronic Disease: a Working Hypothesis. London: H. K. Lewis. 7*s.* 6*d.*

To all about to undertake gastric surgery I commend the careful study of two illuminating contributions to surgical science: Hilton's "Rest and Pain," and Paterson's "The Lure of the New."

I am, Sir, yours faithfully,

Buenos Aires, May 10th, 1925. JOHN O'CONOR.

THE ALLEVIATION OF CHRONIC PROGRESSIVE DEAFNESS.

To the Editor of THE LANCET.

SIR,—We have every reason to be grateful to Mr. George C. Cathcart for calling attention to a form of treatment which deserves much more serious consideration than it has received up to the present. After three years' experience I can fully endorse Mr. Cathcart's favourable view. My results are particularly gratifying in children, in those cases where the middle-ear deafness has not been relieved by the removal of tonsils and adenoids, or by a subsequent course of inflation.

I also should be glad to know more on the subject of the pathological explanation of the improvement in the old-standing cases, as has been mentioned by previous correspondents. The inventor of the apparatus, Mr. Zund-Burguet, himself believes that actual circulatory and nutritive changes occur in the middle-ear structures and cochlea as the result of the intense physiological stimulation. Some change at the peripheral end-organ is likely, as otherwise it is impossible to explain why tinnitus and vertigo disappear. But perhaps the change may be more central, in the nerve paths and synapses linking up the auditory nucleus with the centres in the temporal lobes. These may have been disused for years and are reawakened to function, in which case a true re-education occurs. The improvement could then be explained on the same lines as the improvement in one or both ears which patients very occasionally experience as the result of using the head-phones of the wireless.

I am, Sir, yours faithfully,

Leicester, June 27th, 1925. JOHN A. KEEN.

Obituary.

HENRY GRÆME ANDERSON, M.B.E., M.D. GLASG., F.R.C.S. ENG.

THE sudden death of Mr. H. Græme Anderson, surgical consultant to the Royal Air Force, from angina pectoris on June 28th last removes a capable surgeon from the medical world of London at the early age of 43. Mr. Anderson received his medical education at the University of Glasgow, and in London at King's College and the London Hospital. He graduated M.B., Ch.B. Glasg. in 1904 and five years later obtained the Fellowship of the Royal College of Surgeons of England. In 1919 he gained the M.D. Glasg. with commendation. After graduation Mr. Anderson held hospital appointments for nearly five years, two of which were spent as surgical registrar and pathologist at the Metropolitan Hospital, followed by two years in a similar capacity at St. Mark's Hospital for Cancer and Diseases of the Rectum. At the time of his death he was surgeon to St. Mark's Hospital, senior assistant surgeon to the Belgrave Hospital for Children, and surgical specialist to the Ministry of Pensions. In August, 1914, he joined the Royal Navy as a surgeon lieutenant and was attached as surgeon to the original R.N. Air Service expedition, and was subsequently transferred as major to the Royal Air Force Medical Service. He was appointed surgeon to the British Flying School at Vendôme, France, in 1917, and in 1918–19 was surgeon to the Central R.A.F. Hospital.

Becoming associated with the Royal Naval Air Service early in his period of war service he set about studying the various medical problems of flying with skill and enthusiasm—himself taking a pilot's certificate. Naturally the surgical side claimed his particular attention, although he by no means confined his interests to this, but studied generally the best means of effective selection and care of pilots in the widest sense. In addition to various papers he subsequently embodied his experiences in a valuable book on the "Medical and Surgical Aspects of Aviation" (Oxford Med. Publications, 1919). After the war he resumed practice in Harley-street, but remained surgical consultant to the Royal Air Force, and of him in this capacity Group-Capt. Martin Flack, the Director of Medical Research (R.A.F.), writes: "His services proved of the very greatest value, not only on account of his all-round skill as a surgeon, but on account of the fact that, owing to his intimate acquaintance with aeronautics, he was able also to assess the effect upon flying of various disabilities from the psychological and aeronautical points of view. By his charming personality he earned himself a special place in the affection of his colleagues of the Royal Air Force Medical Service; by his skill he earned the gratitude of his many patients in that service. His early death is a blow to all who were connected with him in these duties, and it can be truly said that he leaves a place which it will be very difficult to fill."

Mr. Anderson, in addition to his work in aviation, made many important contributions to surgical literature dealing with diseases of the rectum. In Burghard's "System of Operative Surgery" he wrote the article on Combined Operations for Excision of the Rectum, and in the "Encyclopædia of Medicine and Surgery for Practitioners," the section on the Rectum. Several papers in the medical journals deal with the treatment of hæmorrhoids.

Mr. J. P. Lockhart-Mummery writes: "Henry Græme Anderson's sudden death is a great blow to all who knew him. He was just at the age when he was coming into the fulfilment of his ambitions, and the results of his many years of hard work were beginning to earn their own reward in steadily increasing practice and reputation. Mr. Anderson was a colleague of mine at St. Mark's Hospital for so long that it is difficult to realise that his ready help and sympathy are no longer available. He was a keen sportsman, and was particularly interested in boxing. There have been few boxing matches of importance in London in recent years at which he was not to be seen at the ring side. He was one of the founders of the Proctological Section of the Royal Society of Medicine, and modern rectal surgery owes very much to Mr. Anderson for the advances of the last ten years.

Mr. Anderson is survived by his widow and a daughter.

WILLIAM JAMES JOHNSTONE STEWART, M.D. EDIN., D.P.H. CAMB.

WE regret to record the death of Dr. W. J. J. Stewart, medical superintendent of the Willesden Municipal Hospital. Dr. Stewart had been in poor health for some time, and his final illness was the result of influenza contracted early this year.

Born in 1868, he studied medicine at the University of Edinburgh and King's College, London, graduating M.B., C.M. Edin. in 1891. Four years later he obtained the D.P.H. Camb., and, in 1896, the M.D. Edin. He devoted his life to the study of infectious diseases and the administration of isolation hospitals, and he was recognised as one of the first authorities on these subjects in the country. During the war he was chosen by the War Office to take charge of the Addington Park War Hospital for soldiers suffering from infectious diseases. He built up and administered this large hospital in a manner which gave the highest satisfaction to both the military and civil authorities concerned. Dr. Stewart had been in the service of the Willesden Council for the past 22 years, and during his period of office the hospital came to be regarded by the public and by the council as one of the best of the municipal institutions of Willesden.

Dr. G. F. Buchan writes of him: "Dr. Stewart's loss will be felt keenly by all his colleagues, for he was a genial man with a kindly heart and ever ready to exert himself and take any amount of trouble to help his juniors and further their interests. Dr. Stewart was one of the many silent workers in the municipal service whose works are more the subject of criticism than of praise, but who nevertheless at all times and in all circumstances perform their duties with a singleness of purpose and conscientiousness which is characteristic of the official life of this country."

Dr. Stewart leaves a widow, to whom we extend our sympathy.

HAMILTON DRUMMOND, M.B., B.S. Durh., F.R.C.S. Edin.

It is with sincere regret that we record the tragic death, at the age of 41, of Mr. Hamilton Drummond, who was one of the best-known surgeons in Newcastle-on-Tyne. Mr. Drummond was the victim of a fatal accident on June 27th, while motoring to Newcastle from Fourstones, where he was serving in his capacity of Major, R.A.M.C.T., at the summer camp of the Northumberland Hussars. It is presumed that his car swerved and so overturned, whereby he sustained a fractured leg and other injuries, and died six hours after the accident. Mr. Drummond was a son of Sir David Drummond, C.B.E., M.D., Pro-Vice-Chancellor of Durham University, and President of the University of Durham College of Medicine. He studied medicine at the Newcastle-on-Tyne School of Medicine and at the London Hospital, graduating M.B., B.S. Durh. in 1906. In 1912 he became a Fellow of the Royal College of Surgeons of Edinburgh. Before taking up practice as a surgeon in Newcastle Mr. Drummond held in succession several valuable house surgeonships, and was a demonstrator of anatomy in University College of Medicine of Durham. From surgical registrar at the Royal Victoria Hospital, Newcastle, he became assistant surgeon to that hospital, and at the time of his death was consulting surgeon to the Jubilee Infirmary, North Shields, the Haltwistle War Memorial Hospital, and the Princess Mary Maternity Hospital, Newcastle.

Mr. Drummond made many contributions to surgical literature, particularly on conditions of the lower bowel.

The late Dr. J. L. Dalby.—Dr. John Lyttleton Dalby, who died at Hove on June 23rd, had practised for a number of years in Brighton and Hove, where he was held in general esteem. He was still in the prime of life, his death following an urgent operation. He was the only son of the late Major Dalby, of Ealing, and studied medicine at St. Bartholomew's Hospital, becoming a licentiate of the Royal College of Physicians in 1894 and M.R.C.S. in the same year.

Hospital Cooking by Electricity.—A new electrical cooking equipment has just come into operation at the Bucks County Mental Hospital at Stone, near Aylesbury, and it is claimed that this is the first asylum to make this departure. Considerable economies are looked for in consequence, and it is said that 17 per cent. of the shrinkage in meat in the course of cooking will be saved. There are over 800 patients, but the equipment is capable of cooking for 1000.

Medical News.

University of Cambridge.—At the Third Examination for medical and surgical degrees held recently the following candidates were examined and approved in the undermentioned subjects:—

Part I., Surgery, Midwifery, and Gynæcology.—A. Barker, W. A. Barnes, I. C. P. Beauchamp, C. B. Buckley, R. C. L'E. Burges, N. F. C. Burgess, J. W. D. Buttery, G. A. H. Buttle, R. T. Chadwick, J. E. Church, D. R. T. Clendon, A. C. Copley, A. F. D. Darlington, J. H. T. Davies, R. K. Debenham, J. V. Dockray, A. Elliot-Smith, V. H. Ellis, C. A. Francis, J. H. Francis, J. A. Galletly, S. E. Gawthrop, J. H. Gibbons, N. M. Goodman, H. W. Gordon, J. L. Groom, K. H. A. Gross, J. H. Hannan, P. M. D'A. Hart, C. H. Hilliard, J. C. Hogg, L. E. Houghton, R. H. Metcalfe, E. F. Malony, J. L. Morgan, H. W. Nicholson, G. F. Oakden, L. V. Pearson, C. P. Pinckney, K. G. Salmon, D. G. Shields, A. Simpson-Smith, H. B. Stallard, R. S. Tooth, K. H. Uttley, and H. M. Woodman.

Part II., Principles and Practice of Physic, Pathology, and Pharmacology.—T. F. Anderson, W. A. Bourne, H. F. Brewer, G. A. H. Buttle, W. E. Chiesman, W. R. F. Collis, H. V. Coverdale, J. E. D. Crozier, C. H. C. Dalton, J. H. T. Davies, P. O. Davies, V. W. Dix, J. M. Doble, H. W. Eddison, J. L. Edwards, A. Elliot-Smith, G. S. W. Evans, K. Fletcher-Barrett, J. H. Francis, P. M. D'A. Hart, N. H. R. Hatfield, R. A. Hickling, J. Holmes, M. C. H. Kingdon, R. L. Lancaster, D. P. Marks, J. P. Marsden, L. P. Marshall, L. M. Maybury, K. F. T. Mills, E. B. Murrell, G. L. F. Rowell, J. Russell Smith, A. J. Smythe, E. W. P. Thomas, S. Vatcher, H. A. Ware, and I. M. Harmer (Girton).

University of Sheffield.—At the undermentioned examinations held recently in the Faculty of Medicine the following candidates were successful:—

M.D.—Clara D. Tingle.

Final M.B., Ch.B.—With Honours: John Wilke (with distinction in Surgery and Gynæcology). Ordinary: Douglas L. Brown, John S. Calcutt, Ralph K. Dowson, Dorothy L. Gregory, Marion Hirst, Wilfrid Malone, Samuel Newsom, George W. Rippon, and Lucy T. Winskill.

Final L.D.S. Examination (Part I.).—George H. Rayner.

University of London.—His Majesty in Council has declared his approval of the amendment of the statute governing the membership of Convocation. Hitherto bachelor graduates have only been able to join Convocation after the expiration of three years from the date of graduation. The attention of Convocation and the Senate was directed to this three years' barrier at the request of the Twentieth Century Society of London Graduates and, under the statute as now amended, all graduates who have attained the age of 21 years are entitled to be registered as members of Convocation.

At a meeting of the Senate of the University of London, held on June 24th, Prof. E. A. Gardner, Litt.D., was re-elected Vice-Chancellor for the year 1925–26.—Correspondence has passed between H.M. Treasury and the University on the subject of the Bloomsbury site. The main outcome of the correspondence is that, as the Treasury is not able to hold out any hope that Parliament could be asked to contribute a larger sum than £370,000, representing the commercial value of the site and buildings of King's College in the Strand, the Senate find themselves compelled to decline the offer, made by the Treasury in 1920, which was accepted by the Senate on the condition that terms of removal would be negotiated between the Government, the Council of King's College, and the Senate of the University. The Senate point out that this condition obviously cannot now be fulfilled.—The title of Emeritus Professor of Hygiene and Public Health in the University was conferred on Sir William J. R. Simpson as from the end of the present session on his retirement from King's College, after 27 years' service, on the closing of the department of bacteriology and public health.—The University Studentship in Physiology for 1925–26, of the value of £50 and tenable for one year in a physiological laboratory of the University or of a school of the University, has been awarded to Mr. Isaac Cohen, Ph.D., B.Sc. He proposes to carry out research on tethelin under the direction of Prof. E. C. Dodds at the Bland-Sutton Institute of Pathology at the Middlesex Hospital Medical School.

University of Paris: Faculty of Medicine.—A post-graduate vacation course in the diseases of children will be held from July 24th to August 14th at the Hôpital des Enfants Malades, 149, Rue de Sévres, Paris, under the direction of Prof. Nobecourt, assisted by Prof. Lereboullet. Lectures and demonstrations will be given twice daily by members of the hospital staff, and an instructional clinic will be conducted each morning by Prof. Nobecourt. The fee for the course is Fr.150. Further information may be obtained from the secretary to the Faculty of Medicine, The University, Paris.

UNIVERSITY OF BRISTOL.—The thesis presented by Francis J. Hector, M.B., Ch.B. Bristol, for the degree of M.D., has been approved by the examiners.

WIRELESS FOR HOSPITALS.—The Wireless for Hospitals Fund, initiated by the proprietors of the *Daily News*, now has between £14,000 and £15,000 in hand, and the advisory council of the fund has decided to equip the largest hospitals first. Twelve of them, beginning with St. Thomas's (630 beds) and ending with the London Temperance (130 beds) are to be supplied as quickly as possible.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE: APPROVED DESIGN.—Mr. P. Morley Horder's design for the new building has been unanimously adopted by the board of management. Competition was limited to five architects who had specialised in the planning and equipment of the type of building required, and Sir Frank Baines, Director of Works at H.M. Office of Works, acted as assessor. Mr. Morley Horder becomes the architect of the building.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The Midland branch of this society proposes to commemorate the knighthood just bestowed upon the medical officer of health for Birmingham by holding a complimentary dinner to Sir John and Lady Robertson at the Queen's Hotel, Birmingham, on Friday, July 10th, at 7 for 7.30 P.M. All members of the Society of Medical Officers of Health are invited to attend this dinner and to bring guests. Early application for tickets (10*s.* 6*d.* not including wines) should be made to Dr. R. H. H. Jolly, hon. secretary, Health Offices, Town Hall, Wolverhampton.

STRASBOURG.—A post-graduate course in dermatology and venereology will be held from Sept. 21st to Nov. 7th, under the direction of Prof. L. M. Pautrier, assisted by Profs. A. Barré, L. Blum, G. Canuyt, Merklen, and others. Complete and practical instruction in all aspects of the specialty will be given at the civil hospital and at the various clinics of the town. The fee is Fr.200. Also a course in laboratory methods and in the general pathological anatomy of the dermatoses will be held if sufficient names are received (minimum, five); the fee will be Fr.150. Full particulars may be obtained from Prof. L. M. Pautrier, 2, Quai St. Nicolas, Strasbourg.

MEDICAL RESEARCH COUNCIL: ROCKEFELLER MEDICAL FELLOWSHIPS.—The Medical Research Council announce that they have awarded Rockefeller Medical Fellowships, tenable in the United States of America during the academic year 1925–26, to the following: Dr. David Campbell, Pollok lecturer in pharmacology and therapeutics, University of Glasgow; Dr. William H. Craib, *M.C.*, house physician, Guy's Hospital, London; Miss Katherine H. Coward, D.Sc., assistant in biochemistry, University College, London; Dr. William S. Dawson, senior assistant, Maudsley Hospital, London; Dr. Howard W. Florey, John Lucas Walker student, University of Cambridge; Mr. Arthur D. Ritchie, lecturer in physiological chemistry, University of Manchester; and Dr. George P. Wright, Macgregor student and demonstrator in histology, University College, London. Dr. Craib, Dr. Florey, and Mr. Ritchie have been appointed on modified conditions while holding scholarships or emoluments from other sources. Mr. Ritchie's Fellowship is being held during a short period of work in Canada this summer.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On July 9th Mr. G. Grey Turner will lecture on Gall-stone Ileus—a Pitfall for the Practitioner, at 5.30 P.M. in the West Lecture Hall, at 1, Wimpole-street, W. The Prince of Wales's General Hospital (North-East London Post-Graduate College, Tottenham, N.) will hold a vacation course from August 4th to the 15th in medicine, surgery, and the specialties. The mornings will include demonstrations of clinical and laboratory methods, in the afternoons groups of illustrative cases, &c., cliniques in the wards and the various out-patient departments. Formal lectures will be given at 4.30 P.M., to which members of the Fellowship of Medicine will be welcomed. Beginning on the same date the All Saints' Hospital will give a month's special course dealing with diseases of the urinary system. Clinical demonstrations will be given and a special lecture each Wednesday afternoon. From August 24th to Sept. 5th the Queen Mary's Hospital, Stratford, have arranged an intensive course in medicine, surgery, and the special departments. A feature of the course is the new department opened for gynæcology and obstetrics. The fee for both intensive courses is £3 3*s.* each, or £2 2*s.* for either week, and for the special course in urology £5 5*s.* Copies of the syllabus of each, together with the Fellowship programme of the general course of instruction available under its scheme, may be obtained from the Secretary at 1, Wimpole-street, W.

WATFORD MEMORIAL HOSPITAL.—Princess Mary last week opened the Watford and District Peace Memorial Hospital of 108 beds, which has been erected at a cost of £60,000.

PRESENTATION OF AN OUT-PATIENTS' DEPARTMENT. An anonymous Wakefield man, now resident in the United States, has promised to provide a new out-patients' department at the Clayton Hospital, Wakefield. Such a department is urgently needed, the existing one being entirely inadequate; last year there were nearly 40,000 attendances.

STREATFEILD RESEARCH SCHOLARSHIP.—Applications are invited for this scholarship which is awarded for the promotion of research in medicine and surgery by a committee of the Royal College of Physicians of London and of the Royal College of Surgeons of England. The scholarship is worth about £250 per annum, and is tenable for three years. Further directions will be found in our advertisement columns.

THE King has sanctioned the following promotions in and appointments to the Order of the Hospital of St. John of Jerusalem in England:—As *Knights of Grace*: Lieut.-Colonel F. S. Lambert, R.A.M.C. (T.); Major-General Sir Samuel Guise Moores; Dr. Frederick J. Waldo; Captain William Thomas Wood, R.A.M.C.; Dr. Arnold Woodford Izard; and Dr. Donald Moore Barry. As *Esquires*: Dr. John Calderwood Strathearn, Dr. Walter Chaloner Rigby, Dr. John Rodley, and Dr. William Haining Curse.

MANCHESTER INFIRMARY: APPEAL FOR NEW NURSES' HOME.—The Manchester Royal Infirmary has issued an appeal for £150,000 to build and equip a new nurses' home which is urgently required for accommodation of an increased staff. The patients in the Royal Infirmary are well nursed, but at a too great cost to the health of the nurses. The day staff works 63 hours a week and the night staff 73 hours. The following data are given for comparison:—

Hospital.	Hours of work.	
	Day.	Night.
Aberdeen..	52	62
Sheffield	56	64
Newcastle	60	69
Manchester	63	73

The board desire to give an all-round working week of 56 hours. The working hours of the maids must also be shortened. In order to do this, 87 additional nurses and 85 additional maids will be required. The nurses, by means of a bazaar, have already raised £5000.

NEW TILBURY HOSPITAL.—Lady Inchcape opened, on June 24th, the new wards of the Tilbury Hospital, erected by the Seamen's Hospital Society on a site rented from the Port of London Authority and within the area of Tilbury Docks. This is an extension of the Passmore Edwards Tilbury District Cottage Hospital founded in 1890, which provides beds not only for seamen, but also for the sick of the surrounding neighbourhood. Of the two new wards, which will accommodate 52 patients, one is for women. Built by Messrs. Mowlem, they were designed by Mr. Stanley Hamp in bungalow style ("not," said Sir Arthur Clarke, the chairman of the society, "that they are a bungle for they are not, but we do owe for them," and, very pertinently, Lady Inchcape thereupon handed to him Lord Inchcape's £500 subscription). The buildings are carried on concrete rafts, and the walls are of hollow triangular cement blocks, hard outside, soft within, securely keyed together. The ceilings are coved and white, but the lower 8 feet of the walls is painted a restful grey which lessens eyestrain. The operating theatre is all white. The floors are also greyish, mottled ("Marvel" flooring), not noisy, of composition similar to the well-known sawdust and gypsum. The bedside lockers are of solid construction and, when turned through a right angle, make steady bed-tables for patients confined to bed. The windows are iron-framed, and in two halves; as the window is opened by the handle, the lower part of the lower half moves outwards and the upper inwards, while the upper sash at the same time moves parallel (lower out, upper in), thus rain is excluded and incoming air directed upwards, so that draughts do not blow on the patients. Angles are all rounded, and the doors are teak, smooth finished to prevent dust lodging; the handles, too, are teak, and the lavatory taps are white-enamelled iron, so there is little to polish anywhere. There is a coal fire in each ward, but otherwise the heating throughout is by radiators, the cooking by gas and steam. In the Nurses' Home each nurse's room has a fixed basin with hot and cold taps over it, and there are sitting and recreation rooms. Two of the beds in the hospital were already endowed, and the chairman was happy in being able to announce that King George's Fund for Seamen would give £1000 to endow another.

THE death of Mr. Thomas Mark Hovell, F.R.C.S. Edin., the well-known laryngologist, at the age of 72 years, is announced as having occurred at Hatfield on June 30th. Mr. Hovell was lecturer on diseases of the throat at the London Hospital and consulting surgeon to the Golden-square Hospital.

THE managers of the Pinsent-Darwin Studentship in Mental Pathology announce that no award has been made this year.

DONATIONS AND BEQUESTS.—Mr. Henry Cornelius Baker, Clifton, Bristol, bequeathed £1000 each to the Bristol Royal Infirmary, the Bristol General Hospital, and Dr. Barnardo's Homes, and £500 each to the Royal Hospital for Women and Children, Bristol, to Müller's Orphanage, and the Bristol Eye Hospital.—During the past month the Royal Manchester Children's Hospital has received subscriptions and donations amounting to £810, including £500 from the Manchester War Memorial Committee.—Sir David Lionel Goldsmid Stern-Salomons, Tunbridge Wells, bequeathed £5000 to Gonville and Caius College, Cambridge, for the fund for increasing the College buildings, and to the Royal Institution some of his scientific apparatus.

ST. BARTHOLOMEW'S HOSPITAL POST-GRADUATE COURSE.—A course of instruction for qualified practitioners will be given at St. Bartholomew's Hospital during the summer vacation from Sept. 7th to 18th inclusive. The object in view is to afford practitioners an opportunity of attending the practice of a large metropolitan hospital and medical college for a short period and of receiving systematic teaching from members of the hospital staff at a time when ordinary lectures and classes for students are in abeyance. A composition fee of ten guineas entitles the practitioner to attend any of the arranged classes as well as the ordinary hospital practice, including wards, out-patients, special departments, operations, and post-mortems. Either of the two weeks may be taken for a fee of six guineas. Application should be made to the Dean, Dr. T. W. Shore, at the Medical College, St. Bartholomew's Hospital, London, E.C.

LANCASHIRE AND CHESHIRE MINERS' CONVALESCENT HOME.—The corner-stones of the convalescent home for the miners of Lancashire and Cheshire, which is to be built at Bispham near Blackpool, was laid on June 20th. The home will be built and equipped out of the Lancashire and Cheshire Welfare Committee's share of the welfare levy of one penny per ton on the coal output for five years, authorised under Section 20 of the Mining Industry Act of 1920. This share on May 31st last, with interest, was £283,406. The estimated cost of the building is about £105,000, and equipment is expected to cost about £20,000. The balance will be invested and the income devoted to the maintenance and upkeep of the home, the site of which is about 7½ acres in extent, facing the sea. The home is planned to accommodate 125 patients, but dormitories for 100 only are at first being provided. Construction was begun in September last and the building is expected to be finished in June next.

"BAY MOUNT," PAIGNTON.—The third annual report gives a clear indication that this comparative newcomer to the ranks of inebriates' homes is rapidly approaching the ideals which have been discussed from time to time in these columns with regard to the treatment of alcohol and drug addicts. The medical superintendent, Dr. Stanford Park, carefully defines what he means by the word "cure"—namely, "that all active craving has been removed and will not come back unless cultivated by the use of alcohol," and then reports that 88 per cent. of those patients classified as curable on admission during the year under review remain cured to date, while 57 per cent. of those classified as incurable have likewise remained free from relapses. It is interesting to note that of the women patients a high proportion of those suffering from alcoholic addiction have undergone some major operation on their reproductive organs. Dr. Park points out with reference to drug addicts that thanks to the Dangerous Drugs Act, patients who are not doctors have little chance of relapsing, and he expresses the hope that as older addicts die off or are cured, drug cases should eventually become extinct."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Select Committee on Nursing Council Rules.

ON Wednesday, June 24th, a Select Committee of the House of Commons was appointed to consider the rules of the General Nursing Council with regard to the prescribed training for nurses and the reservation of seats on the Council for matrons. The following are the members of the Select Committee: Sir R. Barnett, Sir G. Berry, Mr. R. Davies, Mr. Fisher, Lieut.-Colonel Fremantle, Sir C. Forestier-Walker, Mr. G. Hurst, Sir R. Luce, Colonel Sinclair, Miss Wilkinson, and Mr. R. Wilson.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 24TH.

Institutional Treatment of Sleepy Sickness.

Dr. HADEN GUEST asked the Minister of Health whether any special institutional treatment was available for cases of encephalitis lethargica, and whether any special homes are available for cases of children permanently damaged by this disease.—Sir KINGSLEY WOOD replied: My right hon. friend is advised that no special institutional provision is required for cases of this disease in the acute stage, and that such cases may, in general, be properly admitted to isolation hospitals, infirmaries, or general hospitals. As regards the second part of the question, the provision of a special institution for the reception of children suffering from the after-effects of this disease, who cannot be admitted to mental hospitals, is now under consideration.

Proposed Removal of Bethlem Hospital.

Dr. HADEN GUEST asked the Minister of Health whether, in view of the proposed removal of Bethlem Hospital from Southwark to a site outside London, he proposed to call a conference of those interested in the matter with a view to the preservation of the site of Bethlem as a permanent open space.—Sir KINGSLEY WOOD replied: Inquiries made by my right hon. friend have not indicated that any useful purpose would be served by calling a conference, but further attempts will be made to see if this matter cannot be settled without pursuing the controversy which has arisen through a Parliamentary Committee.

Yaws in East Africa.

Colonel DAY asked the Secretary of State for the Colonies whether he was aware of any increase in the prevalence of yaws in East Africa; and, as its cure by intramuscular injections of bismutho potassium sodium tartrate was very inexpensive, being approximately one-tenth of a penny per injection, would he take steps to secure the coöperation of those responsible for the government of Kenya and Tanganyika in order that this bismuth preparation might become available in larger quantities.—Mr. AMERY replied: I am not aware of any increase in the prevalence of yaws in East Africa, but it is undoubtedly serious. The remedy mentioned in the question is referred to in the report of the East African Commission, where reference is made to the delay in utilising in Kenya the experience gained in Tanganyika. But the remedy has been in active use in Kenya for at least three years, and I do not think that any special action is necessary.

THURSDAY, JUNE 25TH.

Deaths from Insect Bites.

Mr. HERBERT WILLIAMS asked the Minister of Health how many deaths were caused in 1924 in England and Wales by the bites of insects.—Mr. N. CHAMBERLAIN replied: There were 12 deaths in England and Wales in 1924 which were caused, according to medical certificate or coroner's inquisition, by the bite of an insect.

Closing of Broad-street Pensions Clinic.

Captain HUDSON asked the Minister of Pensions if he would explain why disabled men were now being sent for treatment to the clinic at Bulinga-street, Millbank, who previously attended the clinic at Broad-street; and if, owing to the inconvenience which would be caused to the disabled men if the Broad-street clinic was closed, he would try to arrange that it should be kept open and the cases for treatment divided between the Bulinga-street and Broad-street clinics.—Major G. C. TRYON replied: The number of cases requiring only out-patient treatment is in the natural course diminishing, and in consequence, though every effort is made to meet the convenience of pensioners, the clinic accommodation has necessarily from time to time to be reduced. The Holborn Clinic belongs to the British Red Cross Society and they have intimated that they cannot continue the clinic unless the number of patients is increased. With the general decline in the number of cases this is not possible and consequently the patients have to be diverted to the more permanent clinics of the Ministry—among others that at Bulinga-street, where I may say the facilities for all varieties of treatment and the means of access are particularly good.

Excessive Rates of Maternal Mortality.

Mr. **GROVES** asked the Minister of Health whether he had considered the report of the chief medical adviser for his department for 1924, in which it was stated that excessive rates of maternal mortality were found in the aggregate in most rural areas, such as Breconshire, Westmorland, Montgomeryshire, Radnorshire, and in highly industrial areas engaged in textile manufacture and coal-mining, and especially in such county boroughs as Halifax, Blackpool, Rochdale, Huddersfield, Swansea, Bradford, Bury, Oldham, Dewsbury, and Blackburn, and whether he proposed any special measures to afford the people of these areas additional medical or institutional treatment in order to remedy this state of affairs.—Mr. N. **CHAMBERLAIN** replied: The answer to the first part of the question is in the affirmative. As regards the second part the authorities of most of the areas mentioned are already taking steps, as a result of the issue of the circular to which I referred in my reply on May 20th, to provide additional facilities for the antenatal examination and institutional treatment of pregnant women, and the medical officers of my department pay special attention to these points on the occasion of their visits to these areas.

Panel Practitioners and Sight-testing.

Mr. **BENNETT** asked the Minister of Health whether he had issued an order that in future optical benefits might only be granted on the certificate of the panel practitioner and after sight-testing by a medical man; and, seeing that the general medical practitioner knew little or nothing of sight-testing, would he say whether he had received any representations on the subject from qualified opticians.—Mr. N. **CHAMBERLAIN** replied: The new model scheme for the provision of ophthalmic benefit by approved societies as an additional benefit contains a provision to the effect that, except in the case of repair or renewal of optical appliances, an applicant for the benefit must have obtained and furnished his society with a written recommendation from a medical practitioner. I have received representations on the subject both from bodies representing opticians and in the opposite sense from representatives of the medical profession, including ophthalmic specialists, and these representations have had due consideration.

Publication of Evidence given to Trevethin Committee.

Mr. **BENNETT** asked the Minister of Health whether he was aware that Colonel L. W. Harrison, of the Ministry of Health, at the Congress of the Royal Institute of Public Health at Brighton, on May 29th, objected to Mr. H. Wansey Bayly, hon. secretary of the Society for the Prevention of Venereal Disease, quoting from the evidence of witnesses before Lord Trevethin's Committee of Inquiry, on the ground that such evidence was confidential; whether the Ministry of Health had received from the Committee of Inquiry any communication to the effect that the evidence of witnesses before that Committee would be treated as confidential; and, seeing that typewritten copies of evidence were being supplied on application to those who gave it without any stipulation being made that such copies were confidential, would he say what was the reason for the non-publication of the evidence before this Committee.—Mr. N. **CHAMBERLAIN** replied: The reply to the first part of the question is in the affirmative and to the second part in the negative. I understand that the Committee decided not to ask for the publication of the evidence.

Danger of Insecticides on Apples.

Colonel **DAY** asked the Minister of Health whether he was aware that Bordeaux mixture (sulphate of copper and lime), containing a proportion of arsenic, was being used as an insecticide on apples; and, as these apples were frequently eaten by children before being cleaned, would he take action to secure the removal of any insecticide deposit before the apples were packed or sold for human consumption.—Mr. N. **CHAMBERLAIN** replied: Yes, sir. The matter has been under the observation of my department for a number of years, but the quantities of arsenic which had been actually found on apples exposed for sale had been so minute as not to justify the institution of special restrictive measures.

Deaths from Ptomaine Poisoning.

Colonel **DAY** asked the Minister of Health whether he was aware of any increase in the number of deaths from ptomaine poisoning, following the eating of tinned foods; and whether the recommendations contained in the report of the Committee of Inquiry on Impure Foods were to be carried into effect.—Mr. N. **CHAMBERLAIN** replied: The number of deaths reported as due to ptomaine poisoning during the five years 1920 to 1924 was 32, 48, 22, 21, and 10 respectively. It is not possible to state in how many of these cases the poisoning was due to the eating of tinned foods, but the numbers can only be a small fraction of the totals already given. A draft of regulations to give effect to the principal recommendations of the Departmental Committee on Preservatives and Colouring Matters in Foods has been published, and I am now considering the form in which the regulations shall be finally made.

Tuberculous Cattle and Sheep.

Lieut.-Colonel **HENEAGE** asked the Minister of Health what percentage of cattle and sheep were found to be tuberculous when slaughtered for food, giving the percentage separately for bullocks, cows, and heifers.—Mr. N. **CHAMBERLAIN** replied: I regret that I cannot give the figures for the whole of the country. The figures given by the medical officer of health for the City of London as regards the Aldgate slaughter-houses (figures which are probably somewhat below the average for the whole country) are as follows:

	1923.	*1924.*
Number of bovine animals slaughtered	38,817	40,058
Percentage found to be tuberculous:		
All bovines	0·31	0·45
Bulls	2·40	4·40
Calves	0·04	0·04
Cows	25·45	28·00
Heifers	11·11	3·10
Oxen	1·20	2·00

Tuberculosis is scarcely ever found in sheep slaughtered for food.

MONDAY, JUNE 29TH.

Ambulance Committee's Recommendations.

Dr. **LITTLE** asked the Minister of Health whether the recommendations of the Ambulance Committee of King Edward's Hospital Fund have received his consideration; and whether he proposed to give effect to them.—Mr. N. **CHAMBERLAIN** replied: So far as these recommendations can be dealt with by administrative action they have been put into operation. So far as they require legislation I fear that they must await the general measure of Poor-law reform which I have in contemplation.

Health of Gold Coast Miners.

Mr. **THURTLE** asked the Secretary of State for the Colonies whether he had yet received the report upon the health statistics of the native mine workers in Gold Coast Colony; and whether it was proposed to publish this report.—Mr. **AMERY** replied: The report has been published on behalf of the Gold Coast Government by the Crown Agents for the Colonies, and copies may be purchased from them. I will place a copy in the library.

Medical Service in African Colonies.

Lieut.-Colonel **ANGUS MCDONNELL** asked the Secretary of State for the Colonies the number of qualified medical officers allowed for in the establishments of the West African Crown Colonies and East African Crown Colonies and Protectorates respectively; whether all the positions were filled; and, if not, what was the number under authorised establishment strength.—Mr. **AMERY** replied: The estimates for the four West African Colonies provide for a total of 246 qualified medical officers. There are at present 32 vacancies after allowing for selected candidates at present under instruction in tropical medicine. In the East African Medical Service, which includes the medical staff of Kenya, Uganda, Nyasaland, Zanzibar, Somaliland and Tanganyika, the authorised strength is 152. There are seven posts unfilled. The medical department of Northern Rhodesia has an establishment of 13 medical officers, and there is one vacancy at present.

Ambulance and First-aid Work at Wembley.

Colonel **DAY** asked the Parliamentary Secretary to the Overseas Trade Department how many trained nurses or trained staff, either men or women, were employed at the ambulance stations of the British Empire Exhibition, and what their remuneration was respectively; who was responsible for engaging them; how many voluntary or semi-trained men and women were employed in this ambulance or first-aid work; what was their remuneration or out-of-pocket expenses, and by whom were these amounts paid; and how many hours each respective class was expected to be on duty.—Mr. A. M. **SAMUEL**, Parliamentary

Secretary to the Overseas Trade Department, replied: I am informed by the British Empire Exhibition authorities that the following trained staff are employed at the ambulance stations of the Exhibition at the rates indicated:—One wardmaster and dispenser at £5 5*s.* per week; one assistant and dispenser at £4 4*s.* per week; one matron at £4 4*s.* per week; and one sister at £3 3*s.* per week. I understand that the wardmaster and the assistant were engaged by the Exhibition authorities, and the matron and sister by the joint committee of St. John's Ambulance and the British Red Cross Society, and that they work eight hours a day. The following semi-trained voluntary workers are also employed: 12 nurses, 45 orderlies, who are provided by the above-mentioned societies alternately a month at a time. I am informed that they work on five-hour shifts and receive an allowance of 2*s.* 6*d.* each per shift for expenses, which is paid by the Exhibition authorities. In addition to the above-mentioned staff there are three qualified medical practitioners.

Local Authorities and House Building.

Mr. RILEY asked the Minister of Health the number of local authorities which have built or are now building houses under the 1924 Housing Act; the number of houses sanctioned under that Act; and the weekly rents charged, exclusive of local rates, for such houses.—Sir KINGSLEY WOOD replied: Four hundred and fifty-nine local authorities in England and Wales have so far received approval to schemes under the Housing (Financial Provisions) Act, 1924, the number of houses authorised being 61,484—59,947 to be erected by the local authorities and 1537 by private enterprise. Of these 4428 had been completed by local authorities and 33 by private enterprise on June 1st; and 15,855 and 184 respectively were under construction at that date. I am advised that in general the rents charged approximate to the rents of houses erected under the Housing, &c., Act, 1923.

Accident in Ammonia Factory.

Miss WILKINSON asked the Home Secretary whether his attention has been drawn to the case of Mr. George Charles Bainbridge, who, as the result of a fall while employed at the works of the Synthetic Ammonia and Nitrates, Limited, of Billingham, was now detained in a mental institution; whether he was aware that no compensation has been paid and that the man was not in receipt of national health insurance; and whether, seeing that the man fell in a doorway near the carbon monoxide plant and that the laboratory at Harrogate, while unable to certify that Bainbridge had been gassed, did contend that he sustained concussion as the result of the fall, he would inquire into this case.—Sir W. JOYNSON-HICKS: I have made inquiries with regard to this case and am informed that after a full hearing the judge accepted the view that the man had been suddenly seized with an acute brain illness which caused him to collapse in the position in which he was found, and decided that his condition was not due to an accident arising out of and in the course of his employment.

TUESDAY, JUNE 30TH.

Ex-Service Men and Tuberculosis.

Brigadier-General BROOKE asked the Minister of Pensions whether he was aware that it was the custom to give ex-Service men whose tuberculosis was admitted as attributable to war service only four weeks' institutional treatment; and, seeing that satisfactory results could not be expected within such a limited period, if he would grant longer periods of treatment.—Lieut.-Colonel G. F. STANLEY replied: My hon. and gallant friend has, I fear, been seriously misinformed. It has been the policy, both of my right hon. friend and of his predecessors, in coöperation with the Ministry of Health, to secure as far as possible preferential treatment for disabled men suffering from tuberculosis due to their war service, and I am glad to say that the average period of in-patient treatment in these cases is not one month, but four months.

SHEFFIELD ROYAL INFIRMARY.—Notwithstanding that 42 new beds have been in daily occupation from the beginning of the year, the waiting-list continues to grow and now numbers 1750. A further 33 beds are being opened immediately.

LEIGH INFIRMARY EXTENSIONS.—The foundation-stones of the Leigh Infirmary extension and the new nurses' home will be laid on July 25th. The total cost for the extensions and for the purchase of additional land, furnishing, and other expenses will be about £30,000. Towards this sum about £23,000 has been collected during the past 18 months. An effort is to be made in the town to raise £7000 in order to open the buildings free from debt.

NATIONAL PHYSICAL LABORATORY:
THE ANNUAL INSPECTION.

AT the invitation of the President of the Royal Society a large number of people gathered at Teddington on June 23rd for the annual inspection by the General Board of the National Physical Laboratory. This occasion affords to many who are interested in science a valuable opportunity to gain an insight into the work of a great scientific institution. The march of science is so rapid that each year sees the expansion of the laboratory which is so essential if progress is to be maintained. Of outstanding interest in this growth may be mentioned the new high voltage laboratory now under erection, which will house the 1,000,000-volt transformer and thus render possible a study of the problems of high voltage electric transmission for which there is an increasing demand. The erection of an adequate laboratory for the Physics Department, at present distributed in three separate buildings, will begin this year, and marks but another step towards increased efficiency. The visitor this year is struck by the increasing application of X rays for the elucidation of the problems presented by the various materials used in industry and science. The medical profession realised from the moment of their discovery the flood of light X rays could throw upon the internal conditions of the human body, and slowly the rays are being turned on all matter revealing information of far-reaching importance.

An inspection of the *Radiology Department* of the laboratory shows how varied are the uses to which X rays are put. The structure of several metals and alloys have been studied by the X ray spectrometer. Laue photographs have been taken of diamonds used as pivot bearings with a view to discovering the conditions necessary to good bearing. Examination for flaws in metals and castings is carried out with a high voltage X ray installation, whilst the rapid elimination of soda glass clinical thermometers is effected by subjecting batches of thermometers to a fluoroscopic test. The increasing application of X rays has led to improvements in X ray tubes and in the methods of obtaining the high vacuum necessary to them. In this work of improvement the Radiology Department continues to play its part. Work in high vacuum research is being continued and an all-steel vacuum pump has been evolved which is compact, simple in use, and possesses distinct advantages over the earlier form produced by the laboratory. Experiments with hot cathode metal X ray tubes of high output are in progress. An experimental tube capable of carrying continuously 30 m.a. at 70 kilovolts has been designed. The tube is permanently attached to a vacuum pumping apparatus and means are adopted whereby targets of different metals may be easily fitted to the tube. The rapid simplification of vacuum pumps leads one to think that soon they will be more widely used in conjunction with gas X ray bulbs to maintain a constant gas pressure under running conditions and thus remove the main objection to this type of tube. Researches on the scattering of the gamma rays of radium, which led to important results last year, are being continued, and measurements of the absorption and scattering coefficients of X rays are being made. The Radiology Department is noteworthy for its complete equipment for routine measurements, enabling on the one hand the accurate determination of the radium contents of tubes and applicators, and on the other the investigation of the lead equivalent and homogenicity of X ray protective materials.

The *Department of Sound* continues to make good progress in the photography of sound by the spark method, and interesting results were shown of the way in which sound is reflected from various types of reflector. The study of the transmission and reflection of sound by partitions is being continued and special chambers have been erected for the work. The ripple-tank method of investigating features of wave reflection has been considerably improved by providing the lamp illuminating the tank with a revolving shutter, which works in synchrony with the tuning-fork vibrator. The intermittent illumination of the tank results in a fascinating stationary picture of the ripples and enables one to study with ease the refraction of waves passing through different thicknesses of liquid. Considerable improvements have been effected in apparatus used for *measuring carbon dioxide in the air of closed spaces such as* the holds of ships. Excessive quantities of carbon dioxide have been found harmful to consignments of fruit, and the need for rapid and simple estimation of the gas has been urgent. Several types of dial-recording instruments have been made, which should find a much wider field of service than that for which they were originally designed.

In the *Department of Heat* the number of clinical and precision mercury thermometers tested remains at approximately the same level as in previous years. In parallel with this testing work, research is being carried out in platinum resistance thermometry and a new type of resistance bridge is being used for the purpose, which allows thermometric measurements of the highest precision to be made.

Of the remaining *Departments of Aero-dynamics, Metallurgy, Metrology, Wireless Telegraphy and Electrotechnics*, the last two are perhaps of more immediate medical interest. That arrangements have been made by the Electrical Department *for the measurement of direct currents up to 10,000 ampères*, and that a 5000-volt direct current set has been installed for the testing of apparatus used in railway equipment is indicative of the wide range of measurement catered for at the laboratory. That the National Physical Laboratory is largely concerned in the pursuit of accuracy is well illustrated in the comparatively new methods for the measurement of radio frequencies, which by the use of quartz resonators give an accuracy of 1 part in 10,000 *for a range of wave-lengths from 25,000 to 30,000* metres.

The National Physical Laboratory is to be congratulated upon its record for the past year and upon the high degree of efficiency and accuracy it has attained in all departments. The laboratory is playing a worthy part in the progress of the national industries.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

MONDAY, July 6th, to SATURDAY, July 11th.—WEST LECTURE HALL, Royal Society of Medicine, 1, Wimpole-street. Lecture arranged by the Fellowship of Medicine and *open to members of the* medical profession. Thursday, July 9th, at 5.30 P.M., Mr. G. Grey Turner: Gallstone Ileus—A Pitfall for the Practitioner.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E. —Special Course in *Diseases* of Children daily from 10 A.M., morning and afternoon sessions covering demonstrations, ward round, out-patient departments, and operations. (First week.)—ST. PETER'S HOSPITAL, Henrietta-street, W.C. Special Course in Urology. Clinical work every afternoon throughout the week. Lectures: Monday, Mr. J. Alban Andrews: Genito-Urinary Tuberculosis; Tuesday, Mr. Swift Joly: *Urinary Calculi*; *Wednesday*, Mr. Clifford Morson: The Technique of Renal Surgery; Thursday, Mr. F. J. F. Barrington: Non-Tuberculous Infections of the Urinary Tract; Friday, Sir John Thomson-Walker: Urinary Obstruction.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, July 7th.—4.30 P.M., Dr. L. R. Yealland: The Diagnosis and Treatment of Functional Nervous Disease.

FRIDAY.—4.30 P.M., Mr. W. Ibbotson: Hoarseness, its Causation and Treatment.

Daily.—Clinics in General and Special Departments. Demonstrations, Operations, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 6th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Donald Armour: Operations.

TUESDAY.—11 A.M., Dr. McDougal: Electrical Dept. 2 P.M., Mr. Tyrrell Gray: Operations. 3 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., *Dr. Burnford: Medical Wards.* 2 P.M., Dr. Dowling: Skin Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., *Sir Henry Simson: Gynæcological* Ward. 12 noon, Surgical Registrar: Surgical Pathology.

FRIDAY.—12 noon, *Dr. Pritchard*: Modern Methods of Medicine. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept. 4 P.M., Dr. Archer: Bio-chemistry.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

THE LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C. 2.

TUESDAY, July 7th.—*5 P.M.*, Dr. *Graham Little*, M.P.: Occupational Dermatoses.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

THURSDAY, July 9th.—*5 P.M.*, Mr. *Lane Roberts*: Clinical Features of Obstructive Labour.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, July 9th.—4 P.M., *Dr.* Robert Hutchison: Diet after the Period of Infancy.

Appointments.

HODGSON, H. K. GRAHAM, M.B., B.S. Durh., D.M.R.E. Camb., has been appointed Honorary Radiologist, King's College *Hospital.*

LANE-ROBERTS, C. S., M.S. Lond., F.R.C.S. Eng., Obstetric Surgeon (with charge of out-patients), Royal Northern *Hospital*, Holloway-road.

MOFFATT, JAMES, M.B., Ch.B. Glasg., Medical Officer of Health to the Durham Rural Council and Medical Officer to the Houghall Isolation Hospital.

ROBINSON, W., M.D., Ch.B. Leeds, Medical Superintendent of the City of London Mental Hospital at Stone, near Dartford.

St. Mary's Hospitals, Manchester: BRIDE, J. W., M.D. Lond. and Manch., Honorary Assistant Surgeon; FERGUSON, R. A., M.B., Ch.B., and JOHNSTONE, MARGUERITE, M.B., Ch.B. Birm., House Surgeons at Whitworth-street West *Hospital*; SHEEHAN, EILEEN, M.B., Ch.B. Manch., and HUMBLE, GRETA E., M.B., Ch.B., House Surgeons at High-street Hospital.

Salford Royal Hospital: WARBURTON, EDWARD J., M.R.C.S., L.R.C.P. Lond., House Surgeon; ALLAN, MALCOLM, M.B., Ch.B. Glasg., Casualty House Surgeon; MAGEE, ANDREW V., M.B., Ch.B. Glasg., House Physician.

University of Manchester: DIGGLE, F. HOLT, F.R.C.S., and LANGLEY, G. J., M.D. Lond., Hon. Assistant Lecturers in Physiology; BRAMWELL, J. CRIGHTON, M.D. Manch., Hon. *Assistant* Lecturer in Experimental Physiology.

Certifying Surgeons under the Factory and Workshop Acts: SMITH, J. W., M.B., Ch.B. Manch. (Borrowash District, Derby), and DUNCAN, A. G. B., M.D. Aberd. (Kidsgrove District, Stafford).

Vacancies.

For further information refer to the advertisement columns.

Birmingham Union, Western-road House and Children's Receiving Homes—Res. M.O. £575.

Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—Res. M.O. £250.

Bradford Royal Infirmary.—Res. Surg. O. £160.

Bolton, Townleys Hospital, Farnworth.—Second Asst. M.O. £225.

Bury County Borough.—Asst. M.O.H., &c. £600.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. at rate of £200.

Croydon County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Eastbourne Royal Eye Hospital.—Hon. Ophth. S.

Edinburgh University.—Chair of Public Health. £1000.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. for six months. £50.

Lanark County.—Bacteriologist and Pathologist. £750.

Liverpool, Brownlow Hill Infirmary.—M.O. £600.

London Hospital Dental School, E.—Asst. Dental Anæsthetists. £25 each.
London Hospital, E.—Two Hon. Asst. Aural S.'s. Also First Asst. to one of the five Surg. Firms. £400.
London Lock Hospital, 283, Harrow-road, W.—Second H.S. £150.
London School of Hygiene and Tropical Medicine.—Four Research Studentships in the Division of Tropical Medicine and Hygiene. £250.
Manchester, Ancoats Hospital.—Hon. Radiologist. Also H.S. at rate of £100.
Manchester, Crossley Maternity Hospital, Ancoats.—Half-time Res. M.O. at rate of £50.
Manchester, St. John's Hospital for the Ear, St. John-street.—Hon. Asst. S.
Manor House Hospital, Golder's Green, N.W.—H.S. £200.
Mansfield Borough.—Asst. M.O.H. £600.
Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—H.S. £150.
National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. P.
New Zealand Government, Mental Hospitals Dept.—Two Asst. M.O.'s. £615.
Norwich, Norfolk and Norwich Hospital.—Res. Anæsth. £150.
Notts Education Committee.—School Dentist. £500.
Royal College of Physicians, Pall Mall East, S.W.—Streatfeild Research Scholar. £250.
Royal College of Surgeons of England.—Examiner in Dental Surgery.
Royal Free Hospital, Gray's Inn-road, W.C.—Obstet. Asst. £50. Obstet. H.S. and Gynæcol. H.S. Also H.P.
Royal Northern Hospital, Holloway, N.—M.O. in charge of Electro-Therapeutic and Massage Dept. 100 guineas. Also S.
Sheffield University and Jessop Hospital for Women.—Asst. Path. and Demonstrator of Anatomy. £300.
Staffordshire Education Committee.—Asst. Sch. Med. Inspector. £600.
Stafford, Staffordshire General Infirmary.—H.P. £150.
Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst Bacteriologist. £E. 720.
Winchester Royal Hampshire County Hospital.—H.P. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Horncastle, Lincs.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Districts of the Consett and Durham County Courts (Circuit No. 2). Applications should reach the Private Secretary, Home Office, London, S.W., not later than July 18th.

Births, Marriages, and Deaths.

BIRTHS.

Phillips.—On June 25th, at "Aspland," Norwich, the wife of Captain Phillips, D.S.O., M.C., R.A.M.C., of a daughter.

Poole.—On June 19th, at South Wigston, Leicester, the wife of Frank S. Poole, M.R.C.S., L.R.C.P., of a son.

Powell.—On June 17th, at Lower Baggot-street, Dublin, the wife of Lieut.-Colonel W. J. Powell, I.M.S., of a daughter.

MARRIAGES.

Cook—Griffith.—on June 25th, in London, Leslie Colin Cook, M.R.C.S., L.R.C.P., to Barbara, eldest daughter of Lieut.-Colonel E. H. Griffith, C.B.E., of Ennismore-gardens, S.W.

Jepson—Defries.—On June 13th, at St. Mary Abbot's, Kensington, Dr. A. C. Jepson, of Bromley, Kent, to Anne Amelia, younger daughter of Mrs. Defries, of Woodlands-avenue, Finchley, N.

Pulford—Thomas.—On June 20th, at the Presbyterian Church, Roath Park, Cardiff, Herbert Pulford, M.A., M.B., B.C. Camb., L.D.S. Eng., to Gertrude Thomas, of Cardiff.

DEATHS.

Anderson.—On June 28th, suddenly, Dr. Harry Græme Anderson, M.B.E., M.D., F.R.C.S., of Harley-street and Malda-vale.

Dalby.—On June 23rd, at Brighton, John Lyttleton Dalby, M.R.C.S., L.R.C.P., aged 55.

Leon.—On June 24th, in London, George Alexander Leon, M.D., aged 68.

Roe.—On June 23rd, at Liverpool, Lieut.-Colonel W. F. Roe, D.S.O., T.D. (R.A.M.C.T.), aged 54.

Ryan.—On June 24th, Charles E. Ryan, M.D., F.R.C.S.I., J.P., Glenlara, Tipperary, aged 75.

Stedman.—On June 24th, at Leighton Buzzard, Percy Taylor Humphrey Stedman, M.B. Lond., M.R.C.S., J.P., aged 48.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HOSPITALS AND THE MILK-SUPPLY.*

By R. Veitch Clark, M.B., B.Sc. Edin., D.P.H.,

MEDICAL OFFICER OF HEALTH TO THE CITY OF MANCHESTER.

The milk-supply is of special importance in hospital work as it forms the main food of patients in the crucial period of their illness. The three main qualities of a good milk-supply are: (*a*) the maintenance of a minimum standard of chemical composition—fats, non-fatty solids, &c.; (*b*) the possession of what are known as the biological properties of milk—i.e., the presence of vitamins, immune bodies, &c.; (*c*) the maintenance of a satisfactory standard of bacteriological purity.

A great deal of work on the immune bodies conveyed in milk has been done both in human milk and in cow's milk. The immunities possessed by the newly born child are very markedly affected by the milk ingested and adults will unquestionably be similarly affected. There is no doubt that in the fight of the body against illness such properties in the food do at times determine the swing of the balance towards recovery when it would otherwise turn against the patient, with general illness as well as with septic and specifically infectious conditions.

Vitamin Content of Milk.—Bacterial Contamination.

Milk contains all three of the main groups of vitamins. The constitution of these substances is not yet known; they can only be recognised by their absence—i.e., by the consequences of their deficiency in food. It would be unjustified to assume that their action is confined to the one avenue suggested by the specific conditions set up by that deficiency. Indeed, the group of fat-soluble vitamins clearly exert a profound influence on the growth and activity of the whole of the bodily organism.

Milk is one of the best media for the growth of practically all of the well-known bacteria, and the processes involved in its production and distribution for general consumption expose it to a degree of contamination which makes it perhaps the least cleanly food in general use. The infection of milk by the bacteria producing the acute infectious fevers, such as enteric fever, scarlet fever, and diphtheria, results in such large and rapidly spreading outbreaks of these diseases, and the danger to the public welfare is so obvious and now so well recognised, that immediate and energetic measures are always taken to eliminate the infected milk from general use and to discover and remove the source of infection. These infections are not, however, constant in milk; they arise as a direct contamination from human sources which, with modern means of investigation, can practically always be discovered. The regularly occurring bacterial contamination of milk is of much greater significance.

Out of 75 samples taken from the general milk-supply of Manchester during 1922–25 tubercle bacilli were found in 12; but no tubercle was present in any sample of the hospital milk. The actual number of bacteria is very greatly less in the latter than in the former, and this diminution of bacterial content is the more striking in that the hospital milk-supplies all come from considerable distances and there is no ice carriage of any description supplied. The conditions only differ from those of the general milk distribution to the public, in that the milk churns have overlapping lids and are sealed at the farm. Over a period of 23 years the results of the examination for tubercle in milk sent to Manchester reveals an average infection with this condition of 9·48, or nearly 1 in 10 of the milk supplied. The incidence of bovine infection varies considerably according to the site affected in man, but to say that tuberculosis of bovine origin accounts for over 50 per cent. of the non-pulmonary tuberculosis of the country is making an extremely conservative statement. It is much more likely that it will account for at least 70 per cent. of the non-pulmonary type of tuberculosis. In the city of Manchester the annual average of non-pulmonary tuberculous conditions notified in persons under 15 years of age during the last 11 years was 494. There is, therefore, a certainty of at least 250 persons being annually infected with tuberculous milk to such an extent as to produce active disease in Manchester alone. These are the cases that are known to the public health authority, and there is no doubt that a very considerable percentage do not come under observation. A significant point is that owing to the impossibility of proper veterinary supervision of the farms during the war the milk did, in these years, show the occurrence of the infection of tuberculosis. This is clear evidence that adequate supervision of farms can eradicate tubercle from the milk-supply. Ordinary careful, skilled supervision can reduce the bacterial contamination of milk a long way towards the standard which has been set by the Ministry of Health in the best of the graded milks established under the Milk (Special Designations) Order, 1923, made under the Milk and Dairies (Amendment) Act, 1922.

---

* Abstract of a paper read at the British Hospitals Association Conference held at Manchester on June 25th, 1925.

The importance of a relatively small bacterial contamination lies in two factors: (1) that bacteriological examination of milk is an extremely exacting gauge of the cleanliness of milk production and milk handling, and (2) that it is an index whereby a reasonable margin of safety can be assured in relation to the incidence of such intestinal diseases as acute or epidemic diarrhœa, and the intestinal troubles which are characteristic of infancy and old age, and the weaknesses of severe illness. That diarrhœa can be controlled by proper handling of milk has been abundantly proved during recent years, more especially in connexion with the remarkable fall in epidemic diarrhœa amongst infants, which is without doubt mainly attributable to the prevention of infection of milks and infant foods, or the measures taken to destroy that infection before such foods are administered to the children.

Over 20 years ago an inquiry was conducted in Yorkshire as to the main source of infection of milk with intestinal organisms, an investigation which was carried out on an extensive scale and with the most meticulous care, and the results showed that the primary and major infection occurred in the cowshed. It is exactly this source of infection that is controlled by the supervision of the source of milk supplied to our hospitals. It is particularly one which can be watched by every hospital authority in the country, and by so doing, and letting it be known generally that it is done, a unique opportunity is afforded to hospital boards of management to act as leaders of thought and action in the public welfare in this matter.

The Hospital Milk-supply in Manchester.

The municipal hospitals of Manchester obtain a satisfactory milk-supply by inserting into the conditions of the contract the following clauses:—

> The milk shall contain not less than 3·25 per cent. of fat and 8·75 per cent. of solids (not fat), and be free from the infective matter of tuberculosis.
>
> The milk must be subject to the approval of the Committee, who will return, at the expense of the contractor, any milk found on delivery to be inferior in quality or in any way unsuitable for the purpose intended, and the contractor will be required to supply other milk of approved quality in place thereof. By way of additional precaution the Committee reserve the right, if they are dissatisfied with the milk delivered or offered for delivery, by resolution, absolutely to cancel the contract.
>
> The milk must be placed in cans and sealed by the farmer before being despatched by train, and on arrival at the station the milk must be especially and immediately despatched to the hospitals, and not taken to any intermediate place. The herd and premises must be at all times open to inspection and examination by the Committee's veterinary officer.
>
> The farm from which the milk is supplied must be kept in a sanitary condition as well as the appliances used, and the process adopted in handling the milk must be satisfactory to the corporation.

There has never been at any time difficulty in getting tenders sent in under these specific conditions, and there is always considerable competition. The price paid for the milk is, as a rule, slightly in excess of the ordinary commercial sale price obtained by the farmer, the extra being paid in respect of special services rendered by the farmer in guaranteeing a definite quantity daily, rather than in respect of any particular condition which the contract places upon him in the manner of milk production. There can be little doubt that if the conditions which Manchester imposes with a view to obtaining a really clean and tubercle-free milk were generally practised throughout the country there would not be any genuine grounds for increase on this account in the price of milk supplied to the public in general.

Farm Conditions.

The veterinary services are supplied to the farmers free, the supervision being carried out by the veterinary surgeon on the staff of the public health department specifically in charge of the city's milk-supply. Such a supervision is unquestionably a public health measure and should be available to the farming community throughout the country, just as the services of the preventive medical staff of the country are available to the public in connexion with general infectious disease. This type of work is clearly undertaken in the interests of the nation at large and should be met out of the national and local purse.

The farms to which the contract is given are inspected by the veterinary surgeon once or twice per month. The herds are examined and all the conditions under which the milk is produced are subjected to careful scrutiny. The churns are of an approved type, with overlapping lid, and are periodically inspected for their soundness and they are each sealed with a red seal before being despatched. In each farm an installation of steam sterilisation for the churn is required. Overalls are worn by the milkers and strict personal cleanliness is required both in the milking and the grooming of the cows. The evening and morning milks must not be mixed. The relationship of the veterinary surgeon to the farmers has always been of an extremely friendly nature and much valuable help and advice is available to the farmer in consequence of this amicable coöperation. Any matters affecting the welfare of the herd, including the feeding, and breeding for increased milk production, have always been an essential part of the work of the veterinary surgeon. In one notable instance the advice as to breeding has resulted in an increase of the yield of milk from about 450 gallons per cow per annum to 700 gallons per cow per annum. No farmer who has had the contract with the hospital has failed to achieve prosperity in his work, the continuous professional advice and help which the farmer has received having reduced sickness amongst the herds.

A valuable aid to the production of a clean and non-injurious milk-supply to the hospitals has been introduced by the practice of supplying to each farmer contracting for the hospitals' supply a copy of the results of the bacteriological examination of all the hospitals' milks, each source of supply being shown separately, but only the individual farmer's own name being mentioned. This stimulates a healthy competition amongst the farmers without giving any detailed information as to the results of the working of farms other than that of the recipient. Unquestionably, raw milk, produced under the best possible conditions, contains all the valuable biological and other ingredients which make milk par excellence the food of infancy, of old age, and of the sick, and it is clearly the duty of every public body to provide for the infirm in hospitals a food supply which is by nature especially fitted to tide them over the dangerous crises of their illnesses. This milk should contain to the fullest possible extent the immune or protective bodies and the vitamins, and any unnecessary and possibly dangerous bacterial contamination should be eliminated.

INCOME-TAX CONCESSION: DEPRECIATION ALLOWANCE ON MOTOR-CARS.

THE Government has now conceded the long-outstanding claim for depreciation and/or obsolescence in respect of motor-cars used by medical men. It will be remembered that on two occasions recently we pointed out the existence of a curious anomaly. The right to claim car wear and tear was confined to traders, and a doctor, whose practice equally necessitated the use of a car, could not claim the same allowance. As long ago as 1920 a Royal Commission recommended that the allowance should not be restricted to traders, and this overdue concession has at last been granted. In future medical men will be allowed each year a percentage of the written-down value of the motor-car. The allowance is usually 20 per cent. and is deducted not from the year's profits, but from the assessment average based on the preceding three years. In the event of a car being wholly dispensed with and replaced by another an allowance is made against that year's profits representing the cost of the car replaced after deducting (1) the total amount of any allowance made for wear and tear, and (2) any sum realised by the sale.

A QUEER STORY.

A CORRESPONDENT writes with indignation of a story entitled "On the Table," which appeared in *Truth* for June 24th. The gist of the story can be told shortly. Two quite recently qualified medical men, one of whom bears the well-known name of a living surgeon, share the operative work of a hospital, each of them alternately operating and giving the anæsthetic. The anæsthetist for the time being, giving chloroform and ether to a feeble old man with malignant gastric ulcer, lets his attention lapse, and finds that the patient has stopped breathing, and is in fact dead. The thrill of the story then occurs.

> "He saw with appalling clearness what would inevitably happen. A death like this, actually upon the operating table, could never pass without an inquest, and an inquest meant the press. In the fraction of a second he saw it all—the headlines, the scandal, the inspired articles demanding protection for the public that could not protect itself, the verdict. That would be favourable, of course, but what would the great British public care for that beside the scandal? It must injure the profession; it must injure the hospital. . . . It was a thing too monstrous to contemplate, by some means or other it must be prevented."

To avoid all this the anæsthetist pretends to surgeon, sister, and nurse that the patient is still living; his abdomen is hastily sewn up, and he is taken back to the ward, artificial respiration being applied the while, the anæsthetist alone keeping his hand on the pulse. Only after return to the ward does he admit that there is no pulse to feel. "I am sorry to say," he says, "that this man has died." "Devilish

Applications should reach the Private Secretary, Home Office, London, S.W., not later than July 18th.

Births, Marriages, and Deaths.

BIRTHS.

PHILLIPS.—On June 25th, at "Aspland," Norwich, the wife of Captain Phillips, D.S.O., M.C., R.A.M.C., of a daughter.

POOLE.—On June 19th, at South Wigston, Leicester, the wife of Frank S. Poole, M.R.C.S., L.R.C.P., *of a son.*

POWELL.—On June 17th, at Lower Baggot-street, Dublin, the wife of Lieut.-Colonel W. J. Powell, I.M.S., of a daughter.

MARRIAGES.

COOK—GRIFFITH.—on June 25th, in London, Leslie Colin Cook, M.R.C.S., L.R.C.P., to Barbara, eldest daughter of Lieut.-Colonel E. H. Griffith, C.B.E., of Ennismore-gardens, S.W.

JEPSON—DEFRIES.—On June 13th, at St. Mary Abbot's, Kensington, Dr. A. C. Jepson, of Bromley, Kent, to Anne Amelia, younger daughter of Mrs. Defries, of Woodlands-avenue, Finchley, N.

PULFORD—THOMAS.—On June 20th, at the Presbyterian Church, Roath Park, Cardiff, Herbert Pulford, M.A., M.B., B.C. Camb., L.D.S. Eng., to Gertrude Thomas, of Cardiff.

DEATHS.

ANDERSON.—On June 28th, suddenly, Dr. Harry Græme Anderson, M.B.E., M.D., F.R.C.S., of Harley-street and Maida-vale.

DALBY.—On June 23rd, at Brighton, John Lyttleton Dalby, M.R.C.S., L.R.C.P., aged 55.

LEON.—On June 24th, in London, George Alexander Leon, M.D., aged 68.

ROE.—On June 23rd, at Liverpool, Lieut.-Colonel W. F. Roe, D.S.O., T.D. (R.A.M.C.T.), aged 54.

RYAN.—On June 24th, Charles E. Ryan, M.D., F.R.C.S.I., J.P., Glenlara, Tipperary, aged 75.

STEDMAN.—On June 24th, at Leighton Buzzard, Percy Taylor Humphrey Stedman, M.B. Lond., M.R.C.S., J.P., aged 48.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HOSPITALS AND THE MILK-SUPPLY.[*]

BY R. VEITCH CLARK, M.B., B.Sc. EDIN., D.P.H.,

MEDICAL OFFICER OF HEALTH TO THE CITY OF MANCHESTER.

THE milk-supply is of special importance in hospital work as it forms the main food of patients in the crucial period of their illness. The three main qualities of a good milk-supply are: (*a*) the maintenance of a minimum standard of chemical composition—fats, non-fatty solids, &c.; (*b*) the possession of what are known as the biological properties of milk—i.e., the presence of vitamins, immune bodies, &c.; (*c*) the maintenance of a satisfactory standard of bacteriological purity.

A great deal of work on the immune bodies conveyed in milk has been done both in human milk and in cow's milk. The immunities possessed by the newly born child are very markedly affected by the milk ingested and adults will unquestionably be similarly affected. There is no doubt that in the fight of the body against illness such properties in the food do at times determine the swing of the balance towards recovery when it would otherwise turn against the patient, with general illness as well as with septic and specifically infectious conditions.

Vitamin Content of Milk.—Bacterial Contamination.

Milk contains all three of the main groups of vitamins. The constitution of these substances is not yet known; they can only be recognised by their absence—i.e., by the consequences of their deficiency in food. It would be unjustified to assume that their action is confined to the one avenue suggested by the specific conditions set up by that deficiency. Indeed, the group of fat-soluble vitamins clearly exert a profound influence on the growth and activity of the whole of the bodily organism.

Milk is one of the best media for the growth of practically all of the well-known bacteria, and the processes involved in its production and distribution for general consumption expose it to a degree of contamination which makes it perhaps the least cleanly food in general use. The infection of milk by the bacteria producing the acute infectious fevers, such as enteric fever, scarlet fever, and diphtheria, results in such large and rapidly spreading outbreaks of these diseases, and the danger to the public welfare is so obvious and now so well recognised, that immediate and energetic measures are always taken to eliminate the infected milk from general use and to discover and remove the source of infection. These infections are not, however, constant in milk; they arise as a direct contamination from human sources which, with modern means of investigation, can practically always be discovered. The regularly occurring bacterial contamination of milk is of much greater significance.

Out of 75 samples taken from the general milk-supply of Manchester during 1922–25 tubercle bacilli were found in 12; but no tubercle was present in any sample of the hospital milk. The actual number of bacteria is very greatly less in the latter than in the former, and this diminution of bacterial content is the more striking in that the hospital milk-supplies all come from considerable distances and there is no ice carriage of any description supplied. The conditions only differ from those of the general milk distribution to the public, in that the milk churns have overlapping lids and are sealed at the farm. Over a period of 23 years the results of the examination for tubercle in milk sent to Manchester reveals an average infection with this condition of 9·48, or nearly 1 in 10 of the milk supplied. The incidence of bovine infection varies considerably according to the site affected in man, but to say that tuberculosis of bovine origin accounts for over 50 per cent. of the non-pulmonary tuberculosis of the country is making an extremely conservative statement. It is much more likely that it will account for at least 70 per cent. of the non-pulmonary type of tuberculosis. In the city of Manchester the annual average of non-pulmonary tuberculous conditions notified in persons under 15 years of age during the last 11 years was 494. There is, therefore, a certainty of at least 250 persons being annually infected with tuberculous milk to such an extent as to produce active disease in Manchester alone. These are the cases that are known to the public health authority, and there is no doubt that a very considerable percentage do not come under observation. A significant point is that owing to the impossibility of proper veterinary supervision of the farms during the war the milk did, in these years, show the occurrence of the infection of tuberculosis. This is clear evidence that adequate supervision of farms can eradicate tubercle from the milk-supply. Ordinary careful, skilled supervision can reduce the bacterial contamination of milk a long way towards the standard which has been set by the Ministry of Health in the best of the graded milks established under the Milk (Special Designations) Order, 1923, made under the Milk and Dairies (Amendment) Act, 1922.

---

[*] Abstract of a paper read at the British Hospitals Association Conference held at Manchester on June 25th, 1925.

The importance of a relatively small bacterial contamination lies in two factors: (1) that bacteriological examination of milk is an extremely exacting gauge of the cleanliness of milk production and milk handling, and (2) that it is an index whereby a reasonable margin of safety can be assured in relation to the incidence of such intestinal diseases as acute or epidemic diarrhœa, and the intestinal troubles which are characteristic of infancy and old age, and the weaknesses of severe illness. That diarrhœa can be controlled by proper handling of milk has been abundantly proved during recent years, more especially in connexion with the remarkable fall in epidemic diarrhœa amongst infants, which is without doubt mainly attributable to the prevention of infection of milks and infant foods, or the measures taken to destroy that infection before such foods are administered to the children.

Over 20 years ago an inquiry was conducted in Yorkshire as to the main source of infection of milk with intestinal organisms, an investigation which was carried out on an extensive scale and with the most meticulous care, and the results showed that the primary and major infection occurred in the cowshed. It is exactly this source of infection that is controlled by the supervision of the source of milk supplied to our hospitals. It is particularly one which can be watched by every hospital authority in the country, and by so doing, and letting it be known generally that it is done, a unique opportunity is afforded to hospital boards of management to act as leaders of thought and action in the public welfare in this matter.

The Hospital Milk-supply in Manchester.

The municipal hospitals of Manchester obtain a satisfactory milk-supply by inserting into the conditions of the contract the following clauses:—

> The milk shall contain not less than 3·25 per cent. of fat and 8·75 per cent. of solids (not fat), and be free from the infective matter of tuberculosis.
>
> The milk must be subject to the approval of the Committee, who will return, at the expense of the contractor, any milk found on delivery to be inferior in quality or in any way unsuitable for the purpose intended, and the contractor will be required to supply other milk of approved quality in place thereof. By way of additional precaution the Committee reserve the right, if they are dissatisfied with the milk delivered or offered for delivery, by resolution, absolutely to cancel the contract.
>
> The milk must be placed in cans and sealed by the farmer before being despatched by train, and on arrival at the station the milk must be especially and immediately despatched to the hospitals, and not taken to any intermediate place. The herd and premises must be at all times open to inspection and examination by the Committee's veterinary officer.
>
> The farm from which the milk is supplied must be kept in a sanitary condition as well as the appliances used, and the process adopted in handling the milk must be satisfactory to the corporation.

There has never been at any time difficulty in getting tenders sent in under these specific conditions, and there is always considerable competition. The price paid for the milk is, as a rule, slightly in excess of the ordinary commercial sale price obtained by the farmer, the extra being paid in respect of special services rendered by the farmer in guaranteeing a definite quantity daily, rather than in respect of any particular condition which the contract places upon him in the manner of milk production. There can be little doubt that if the conditions which Manchester imposes with a view to obtaining a really clean and tubercle-free milk were generally practised throughout the country there would not be any genuine grounds for increase on this account in the price of milk supplied to the public in general.

Farm Conditions.

The veterinary services are supplied to the farmers free, the supervision being carried out by the veterinary surgeon on the staff of the public health department specifically in charge of the city's milk-supply. Such a supervision is unquestionably a public health measure and should be available to the farming community throughout the country, just as the services of the preventive medical staff of the country are available to the public in connexion with general infectious disease. This type of work is clearly undertaken in the interests of the nation at large and should be met out of the national and local purse.

The farms to which the contract is given are inspected by the veterinary surgeon once or twice per month. The herds are examined and all the conditions under which the milk is produced are subjected to careful scrutiny. The churns are of an approved type, with overlapping lid, and are periodically inspected for their soundness and they are each sealed with a red seal before being despatched. In each farm an installation of steam sterilisation for the churn is required. Overalls are worn by the milkers and strict personal cleanliness is required both in the milking and the grooming of the cows. The evening and morning milks must not be mixed. The relationship of the veterinary surgeon to the farmers has always been of an extremely friendly nature and much valuable help and advice is available to the farmer in consequence of this amicable coöperation. Any matters affecting the welfare of the herd, including the feeding, and breeding for increased milk production, have always been an essential part of the work of the veterinary surgeon. In one notable instance the advice as to breeding has resulted in an increase of the yield of milk from about 450 gallons per cow per annum to 700 gallons per cow per annum. No farmer who has had the contract with the hospital has failed to achieve prosperity in his work, the continuous professional advice and help which the farmer has received having reduced sickness amongst the herds.

A valuable aid to the production of a clean and non-injurious milk-supply to the hospitals has been introduced by the practice of supplying to each farmer contracting for the hospitals' supply a copy of the results of the bacteriological examination of all the hospitals' milks, each source of supply being shown separately, but only the individual farmer's own name being mentioned. This stimulates a healthy competition amongst the farmers without giving any detailed information as to the results of the working of farms other than that of the recipient. Unquestionably, raw milk, produced under the best possible conditions, contains all the valuable biological and other ingredients which make milk *par excellence* the food of infancy, of old age, and of the sick, and it is clearly the duty of every public body to provide for the infirm in hospitals a food supply which is by nature especially fitted to tide them over the dangerous crises of their illnesses. This milk should contain to the fullest possible extent the immune or protective bodies and the vitamins, and any unnecessary and possibly dangerous bacterial contamination should be eliminated.

INCOME-TAX CONCESSION: DEPRECIATION ALLOWANCE ON MOTOR-CARS.

THE Government has now conceded the long-outstanding claim for depreciation and/or obsolescence in respect of motor-cars used by medical men. It will be remembered that on two occasions recently we pointed out the existence of a curious anomaly. The right to claim car wear and tear was confined to traders, and a doctor, whose practice equally necessitated the use of a car, could not claim the same allowance. As long ago as 1920 a Royal Commission recommended that the allowance should not be restricted to traders, and this overdue concession has at last been granted. In future medical men will be allowed each year a percentage of the written-down value of the motor-car. The allowance is usually 20 per cent. and is deducted not from the year's profits, but from the assessment average based on the preceding three years. In the event of a car being wholly dispensed with and replaced by another an allowance is made against that year's profits representing the cost of the car replaced after deducting (1) the total amount of any allowance made for wear and tear, and (2) any sum realised by the sale.

A QUEER STORY.

A CORRESPONDENT writes with indignation of a story entitled "On the Table," which appeared in *Truth* for June 24th. The gist of the story can be told shortly. Two quite recently qualified medical men, one of whom bears the well-known name of a living surgeon, share the operative work of a hospital, each of them alternately operating and giving the anæsthetic. The anæsthetist for the time being, giving chloroform and ether to a feeble old man with malignant gastric ulcer, lets his attention lapse, and finds that the patient has stopped breathing, and is in fact dead. The thrill of the story then occurs.

> "He saw with appalling clearness what would inevitably happen. A death like this, actually upon the operating table, could never pass without an inquest, and an inquest meant the press. In the fraction of a second he saw it all—the headlines, the scandal, the inspired articles demanding protection for the public that could not protect itself, the verdict. That would be favourable, of course, but what would the great British public care for that beside the scandal! It must injure the profession; it must injure the hospital. . . . It was a thing too monstrous to contemplate, by some means or other it must be prevented."

To avoid all this the anæsthetist pretends to surgeon, sister, and nurse that the patient is still living; his abdomen is hastily sewn up, and he is taken back to the ward, artificial respiration being applied the while, the anæsthetist alone keeping his hand on the pulse. Only after return to the ward does he admit that there is no pulse to feel. "I am sorry to say," he says, "that this man has died." "Devilish lucky for us," the surgeon rejoins, "that fellow did not die on the table."

It is quite wrong to suppose that the patient's death in bed subsequent to the operation would avoid the necessity of informing the coroner. The crucial point, of course, is not where the patient died, but whether he was still under the anæsthetic. Newly qualified house surgeons at hospitals in this country do not perform major abdominal operations. No doubt the attention of a house surgeon, as of any other human being, may lapse sometimes, but this simply could not occur *during* the administration of an anæsthetic. The story is written by someone without adequate knowledge.

THE TRAFFIC IN WOMEN AND CHILDREN.

THE presidents of the great women's associations throughout the world have been circularised with an inquiry as to the conditions obtaining in their respective countries in regard to the traffic in women and children. The League of Nations has now published a summary of the replies received, prepared by Mme. Avril de Sainte Croix. The answers reveal unanimity of opinion throughout the world and a general sense of need for coördination of preventive work. Its contents are already too condensed to be abstracted here and the pamphlet should be consulted by all interested in the subject. Information is given of the conditions of women in South Africa, Austria, Belgium, Canada, Denmark, America, Finland, France, Great Britain, Hungary, Greece, Latvia, New South Wales, Norway, Holland, Poland, Portugal, and Czecho-Slovakia.

AN IMPROPER SUGGESTION.

A MEDICAL man sends us a letter which he has received from the patentees and sole makers of a new self-adjusting truss for hernia, stating that several of these trusses have recently been sold direct to doctors, and have, they are assured, given complete satisfaction to the wearers. "We shall be happy," the letter concludes, "to send the truss quite free of expense for your inspection and to allow you 15 per cent. on sales." The suggestion in the last sentence is improper. The sale of any appliance on a doctor's recommendation is dependent on the patient's belief that the recommendation is based solely upon the merits of the article recommended.

INCOME-TAX ALLOWANCES.

To the Editor of THE LANCET.

SIR,—I am quite sure in my own mind that medical practitioners often overpay income-tax, and I think that here THE LANCET might be of assistance. Would it be possible to ask readers to send for your private information—unless no objection to publicity was mentioned—a list of the various allowances made to them by their local inspectors? The capricious nature of the demands made would then, in my opinion, become clear, as well as the fact that they had not infrequently been met without protest. If you could give help to readers, based on such evidence in reply to definite questions, we should many of us be very much obliged.

I am, Sir, yours faithfully,
A MEDICAL PRACTITIONER.
July 1st, 1925.

AN UNREGISTERED APPLICANT.

To the Editor of THE LANCET.

SIR,—I understand that advertisements for an assistant or a locum tenens have been answered by Mr. K. R. G. Shaw. Practitioners should be warned that, before engaging him, it is desirable that inquiry as to his registration should be made at the office of the General Medical Council.

I am, Sir, yours faithfully,
NORMAN C. KING,
Registrar, General Medical Council.
44, Hallam-street, Portland-place, London, W.,
June 26th, 1925.

COMPULSORY ISOLATION OF INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—Quite recently in discussion I learned from a medical man in a rural district, and also from a member of a rural district council, that medical men possessed no power in rural areas to segregate cases of dangerous disease. I also obtained evidence that doctors and sanitary inspectors who had provided facilities for the removal to isolation hospitals of dangerous infectious cases were powerless in the face of ignorant opposition offered by parents and others It may be news to the public in general, and to some member of the medical profession, that doctors actually possess the requisite powers under a 50-year-old Act of Parliament.

For your information I beg to quote from a letter received by me from the Secretary of the Ministry of Health, dated June 19th, as follows :—

"I am to state that patients suffering from any dangerous infectious disorder, whether in urban or rural districts, can only be removed compulsorily to hospital in accordance with the provisions of Section 124 of the Public Health Act, 1875. That section provides for the compulsory removal of patients in certain circumstances by an order of a justice on a certificate signed by a legally qualified medical practitioner. With regard to the alleged failure to isolate patients treated in their homes, I am to refer you to Section 126 of the Public Health Act, 1875, under which, in the case of any dangerous infectious disorder, penalties are prescribed for the exposure, without proper precautions, of infected persons."

I am, Sir, yours faithfully,
HERBERT MOORE PIM.
Cley, Norfolk, June 22nd, 1925.

⁂ It should be common knowledge in the health service that Section 124 of the Public Health Act, 1875, allows a justice's order to be obtained for persons "without proper lodging or accommodation," and a higher court has decided that magistrates in considering "proper accommodation" may pay regard to "means of isolation." This section has been used for the compulsory removal of badly-housed cases of scarlet fever and typhoid, but the mere threat to use it is usually sufficient.—ED. L.

SALE OF BIOLOGICAL DRUGS UNDER LICENCE IN THE U.S.A.

THE issue of *Public Health Reports* for May 29th, 1925, issued by the United States Public Health Service, contains a revised table of the establishments holding licences issued by the Treasury Department in accordance with an Act of Congress of July, 1902, entitled "An Act to regulate the sale of viruses, serums, toxins, and analogous drugs in the district of Columbia, to regulate inter-State traffic in said articles, and for other purposes." The licences granted do not imply an endorsement of the claims made by the manufacturers, but the granting of a licence does mean that inspection of the establishment concerned and laboratory examinations of samples of its products are made regularly to ensure the observance of safe methods of manufacture, to ascertain freedom from contamination, and to determine the potency of those drugs for which standards or tests have been established. The American licensed establishments in this list number 36. Of foreign establishments the *Report* enumerates the following, in each case specifying the products for which licences have been issued.

Institut Pasteur de Paris. Diphtheria antitoxin; tetanus antitoxin; anti-anthrax serum; anti-dysenteric serum; anti-plague serum; anti-streptococcic serum; bacterial vaccines made from cholera vibrio, plague bacillus, *Staphylococcus albus*, and *Staph. aureus*.

Farbwerke Hoechst (vorm. Meister, Lucius and Brüning), Hoechst am Main. Diphtheria antitoxin; tetanus antitoxin; anti-streptococcic serum; normal horse serum; tuberculin old; tuberculin T. R.; tuberculin B. E.; tuberculin B. F.; bacterial vaccines made from cholera vibrio, gonococcus, *Staphylococcus albus*, *Staph. aureus*, and *Staph. citreus*; typhoid bacillus; sensitised bacterial vaccine made from typhoid bacillus; arsphenamine; neoarsphenamine; sodium arsphenamine; silver arsphenamine; neosilverarsphenamine; sulphoxylarsphenamine.

E. Merck, Darmstadt. Tuberculin ointment (Moro).

Connaught Antitoxin Laboratory, University of Toronto, Canada. Diphtheria antitoxin; tetanus antitoxin.

Les Etablissements Poulenc Frères, 92, Rue Vieille-du-Temple, Paris, III. Bacterial vaccines made from gonococcus, *Micrococcus tetragenus*, pertussis bacillus, *Staphylococcus albus*, *Staph. aureus*, and *synococcus*.

Laboratoire de Biochemie Médicale, 92, Rue Michel-Ange, Paris. Sulpharsphenamine.

Istituto Sieroterapico Milanese, Milan. Anti-anthrax serum, bacterial vaccines made from gonococcus, pneumococcus, *Staphylococcus albus*, *Staph. aureus*, *Staph. citreus*, and streptococcus; neoarsphenamine. Selling agents for the United States: Neother Products Co., 50, Union-square, New York City.

Boots Pure Drug Co., Ltd., Nottingham. Arsphenamine Diglucoside.

Etablissements Mouneyrat, Villaneuve-la-Garenne, Seine. Phospharsphenamine.

Institut National de Vaccinotherapie, 26, Rue Pages, Suresnes (Seine): Bacterial vaccines made from colon bacillus, enterococcus, Friedländer bacillus, *Micrococcus catarrhalis*, *Micrococcus tetragenus*, pneumococcus, *Staphylococcus albus*, *Staph. aureus*, and streptococcus.

Behringwerke, A. G., Marburg-am-Lahn. Bacterial vaccines made from gonococcus, *Staphylococcus albus*, and *Staph. aureus*.

THE

Croonian Lectures

ON SOME

DISORDERS OF MOTILITY AND OF *MUSCLE TONE*,

WITH SPECIAL REFERENCE TO THE CORPUS STRIATUM.

Delivered before the Royal College of Physicians of London

BY S. A. KINNIER WILSON, M.D., B.SC. EDIN., F.R.C.P. LOND.,

PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE; JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

LECTURE II.*

MR. PRESIDENT AND GENTLEMEN,—Hitherto our investigation of the characteristics of "voluntary" movement in affections of the corpus striatum has been prosecuted on general lines. It is time to turn to a more precise examination of individual "voluntary" acts for differing parts of the body musculature, as an essential preliminary to an analysis of various kinds of so-called "involuntary" movement occurring in these diseases. There is the more need for this investigation in that we are now approaching a clinical field where confusion reigns supreme in respect of nomenclature. Among the tangled mass of movements described by different observers as "primitive automatisms," "higher coördinations," "associated movements," "position alterations," "reaction reflexes," "reflex synergias," "movement synergias," "associated reactions," "automatised voluntary movements," "reaction movements," and what not, the student may well be excused if he loses his way. (The above terms have been culled *verbatim* from the pages of various writers on the subject and might be added to considerably.) The need for classification is urgent, but it can be met only by first analysing normal movement and by coming to a decision on definitions.

BEHAVIOUR OF MUSCULAR COMPONENTS OF "VOLUNTARY" MOVEMENT IN STRIATAL DISEASE.

I have already indicated the lines I shall follow in this connexion. I shall take a normal movement to have as constituents the actions of prime movers or protagonists, synergists (including fixation muscles), and antagonists respectively. I shall not call the whole a "synergic unit," or a "movement synergia," but simply a movement, with the component parts just enumerated.

The following are the single or combined movements that have been studied in normal persons and in a large number of cases coming into the category of striatal disease:—

I. Head, face, and neck.

1. Shut eyes, with or without resistance; eyeballs roll up.
2. Turn eyes to side; head turns also.
3 Open mouth, *against resistance*; head extends.
4. Turn eyes up; forehead wrinkles, head extends.
5. In supine position, flex head on chest; recti abdominis contract.
6 Flex head against resistance; platysmas, omohyoids, hyoid depressors contract.
7. With head in one extreme lateral position (say, right) rotate it slowly to left; left posterior rotators contract first, and right sternomastoid only after head is well past the mid-line. And vice versa.

II. Shoulder, arm, hand, and fingers.

1. Abduct extended arm at shoulder; opposite erector spinæ contracts.
2. Adduct extended arm from horizontal position; homolateral rectus abdominis and erector spinæ contract (only if against resistance).
3. In erect position, advance extended arm to horizontal level in front—both erectores spinæ contract; rotate it horizontally backwards—homolateral erector spinæ at once relaxes; bring it forward again on horizontal level—the same erector spinæ contracts again; depress extended arm once more to side—homolateral erector spinæ once more relaxes.
4. With arm flexed at elbow and forearm pronated, supinate (biceps does this); triceps contracts to prevent further flexion at elbow.
5. Flex fingers in grasping; extensors of wrist contract. Increase grasping movements; triceps contracts.
6. Open closed hand; extensors of wrist relax; flexors of wrist contract.
7. Extend wrist with fingers closed—extensores carpi radiales and ulnaris contract; without stopping wrist extension, open fingers—the wrist extensors at once relax, while the extensors of the fingers continue the upward movement.
8. Press thumb firmly against forefinger; flexor carpi ulnaris contracts.
9. Abduct little finger; *extensor ossis metacarpi pollicis* contracts.
10. Extend thumb; extensor and flexor carpi ulnaris contract.
11. Abduct forefinger; thumb nearly always flexes or adducts and, if so, extensors of thumb contract.

III. Trunk and legs.

1. Supine position; lift one extended leg (i.e., flex at hip); contralateral hamstrings (internal or external group, or both) contract.
2. Supine position; lift head and shoulders up; recti abdominis contract, then both recti femoris.
3. Erect position, abduct one extended leg at hip; opposite tensor fasciæ femoris contracts.
4. Flex spine—i.e., bend forwards (not against resistance); both erectores spinæ contract.
5. Bend backwards—i.e., extend spine; recti abdominis contract. Combining (4) and (5), recti and erectores alternately contract and relax.
6. Incline spine to right or left; opposite erector spinæ contracts.

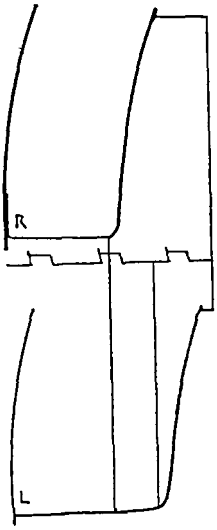
This scheme contains a description of the precise behaviour of muscular components in a number of normal movements and movement-combinations, and has been carried out *in extenso* in many examples both of paralysis agitans and of postencephalitic Parkinsonism.

With minor qualifications to be referred to immediately, *my definite conclusion is, that these movements are executed normally by Parkinsonians—that is to say, the movements follow normal physiological lines and are neither lost nor perverted.* I have not seen a single instance either of failure to perform the movement (except as below), or of interference with normal physiological order. In what might be termed "movements of sequence" (viz., I. 7, II. 7, III. 5 above), I have not found any departure from the normal. By this term I mean movements which are begun by one muscle or muscular group and continued by another. My former chief, the late Dr. C. E. Beevor, devoted attention to these, showing the order of action to be so fixed physiologically that it cannot be voluntarily modified, and that if one muscle in the total act fails its place cannot readily be taken by another which might appear suitable for the purpose. He said, "it rather reminds one of some highly organised establishments where if one of the servants is incapacitated it is no one's place to do the work, which is consequently left undone." The qualifications I would make are, that if the action of the agonists is inherently weak that of the other components is correspondingly feeble and therefore difficult to recognise, though as a general rule the introduction of an element of resistance against which to work intensifies the "voluntary" effort and so may bring out the constituents better. For example, I find that the triceps often will not partake in the hand-grasping movement (II. 5 above) because the latter cannot be executed with sufficient power. Further, some of the finger movements specified above, notably abduction of the little finger, may *in fact almost fail, for reasons already sufficiently* gone into. Again, in some normal persons part of the movement is facultative rather than obligatory—e.g., in I. 4 the forehead may not wrinkle; we must avoid, therefore, an overestimation of such "loss" in Parkinsonian cases. The study of these movements, finally, in seriously advanced cases of the disease is open to the objection that myogenic contractions may have set in, and this will naturally vitiate the clinical findings.

---

* Lecture I. appeared in THE LANCET last week.

FIG. 12.



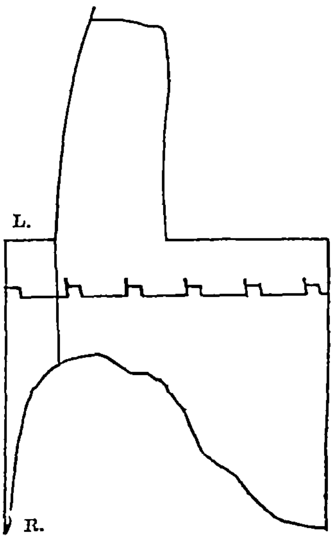
Curves of contraction of the recti femoris in the combined movement of sitting up from a supine position. Unilateral Parkinsonian case. The affected muscle (left) contracts about three-quarters of a second later than that on the normal side.

The main conclusion stands, and has weight. I find myself, therefore, unable to confirm in a general sense the observations of Foerster, who states that in pallidal cases (as he calls them) the eyes do not roll up when they are closed against resistance, the head does not move when the eyes are deviated laterally, and so on. As a consequence, *the theory according to which the "loss" of these "Mitbewegungen"* (an unfortunate terminology), *in reality the components in a total single movement, is held to prove that the corpus striatum is a "centre" for their normal activation, is shown to be based on erroneous observation and to have no foundation in fact.*

I may take this chance of again entering a caveat against the view that because muscular action is hindered or encounters obstacles it is *pro tanto* "lost." In some instances of excessive muscular rigidity, especially among postencephalitic cases, the movement of the head accompanying lateral deviation of the eyes is minimal, yet to describe it as "lost" and at the same time to ignore the multiplicity of factors in Parkinsonian immobility would be a mistake. Of the comparative slowness with which the above enumerated movements are sometimes performed there can, of course, be no question, nor of the frequent weakness of some of them. In respect of the slowness, the records from unilateral cases of postencephalitic Parkinsonism are instructive. In the movement of raising the shoulders from the supine position (III. 2 above) the normal individual contracts both recti femoris simultaneously and within a very brief period after the shortening of the recti abdominis. In unilateral cases delay in the contraction of the rectus femoris on the affected side has been constantly found, but I have failed to note any difference in this respect in that of the twin recti abdominis. For example, Fig. 12 gives a tracing from a case of this kind, showing on the Parkinsonian side a delay of about three-quarters of a second in the contraction of the muscle on the front of the left thigh compared with that on the right (unaffected) side. Fig. 13 gives another record of the same kind, where the difference in time of contraction is almost one second. The fact that I have found no certain distinction in rate of contraction between the two recti abdominis (once or twice a very slight retardation on the affected side has seemed present) is doubtless to be explained by the physiological unity of the two (though to this there are exceptions), according to Broadbent's hypothesis. But the difference in the case of the two recti femoris is striking. Their rôle in the movement is that of accessory prime movers; arising from the ilium, they are flexors of the hip and their shortening serves to bring the pelvis into a more vertical position. No delay in contraction took place as regards the first prime movers (recti abdominis) in the cases from which the tracings were obtained, no doubt owing to their bilateral innervation. The two recti femoris contract with equal *power*, as the curves indicate; and when the patient is given the order to lie down again it is seemingly the healthy muscle that decontracts the more slowly, the Parkinsonian muscle relaxing faster (Fig. 13). No trace of tonic innervation or of slow relaxation with a "lengthening reaction" is here observable.

In some instances from my records, on the other hand, weakness is discernible while slowness of contraction or relaxation cannot be detected. We have seen (II. 6 above) that when the closed fist is opened the extensors of the wrist immediately relax while the extensors of the fingers contract. Fig. 14 shows the constituent actions as they occur in the normal individual, relaxation of the former and contraction of the latter being practically simultaneous. Figs. 15 and 16 are from cases of Parkinson's disease; in Fig. 15, on the signal given, the wrist extensors are seen to relax at the same moment as the finger extensors contract, without any retardation, and notwithstanding the obvious tremor with which the movement is accompanied. In Fig. 16 the lower tracing shows clearly the gradual weakening of the contraction of the wrist extensors before the signal—in other words, the *inability to maintain an innervation* which often characterises Parkinsonism. On the signal, however, the normal procedure at once occurs, though the decontraction of the wrist extensors is fractionally slower than the contraction of the finger extensors and exhibits the so-called "cogwheel" phenomenon (to be afterwards discussed).

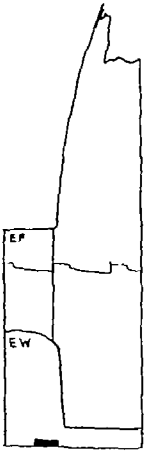
FIG. 13.



Similar to Fig. 12. Unilateral Parkinsonian case. The rectus femoris of the normal side (right) contracts before the other and also takes longer to decontract as the patient lies back again.

Equally instructive are the tracings of the combined movement described under II. 3 above. The extended arm (say, left) is advanced to the shoulder level in front, swept back in a circle-arc on this horizontal level, brought forward again, then down to the side. As this is being done the left erector spinæ contracts, relaxes, contracts again, relaxes again. Fig. 17, from a normal individual, is to be compared with Fig. 18, from a severe case of chronic postencephalitic Parkinson syndrome. It must be borne in mind, to understand the meaning of the tracings, that in the erect position the erectores spinæ of the normal person are not in action; in the Parkinsonian, with his typical forward inclination of the trunk, they are, on the contrary, in strong ("involuntary") contraction. Now when the two records are examined the reader will see that, notwithstanding the steady "postural" contraction of the spinal muscle in the Parkinsonian, its successive "voluntary" contraction and relaxation follow normal physiological lines; it rises and falls exactly as does the normal erector spinæ, at the appropriate signals. Particularly instructive are the two points (1) that at the beginning of the "voluntary" movement the already posturally contracted erector spinæ *contracts still further;* (2) that when it is beginning to relax normally as the movement is coming to a close it springs again into this steady "involuntary" contraction. (Although the Parkinsonian record is slower than the other the two are not in this respect comparable, since no attempt was made to have the patient perform the movement quickly.) The actions of the erector spinæ during the execution of the combined movement are not characterised either by undue retardation or by limitation of range; that is to say, that component of a "voluntary" movement of the synergic action of which the patient is quite unaware (no one in thus advancing and rotating *the arm has any idea that the* erector spinæ constantly partakes therein), and which, as indicated at the outset, is "involuntary" in the sense that it is inevitable and largely outside consciousness, can and does impress itself on the existing background of postural "involuntary" contraction, modifying the latter in the course of its own appropriate action. A single instance of this description shows incidentally the unsatisfactory character of the usual distinctions drawn between "voluntary" and "involuntary," for we have here the idea of *degrees of involuntariness*, one major and the other minor, one part of a so-called "voluntary" act, the other part of a so-called postural contraction. Further, these illustrations serve to lend point to the statement made in the introduction, that in objective characters, clinically speaking, "voluntary" movements are not to be distinguished from those in which the element of "volition" is lacking. Neither the examiner's finger nor the myographic tracing reveals any difference between the contraction of the erector spinæ at (*c*) (Fig. 18), and at (*d*) (same Fig.), but the former, according to the usual conceptions, is "voluntary" and the latter "involuntary." As a clinician, I cannot say where "volitional" activity ends and "non-volitional" activity begins.

FIG. 14.



Normal hand, with fist closed "voluntarily." On the signal ("open the hand") the extensors of the fingers contract and the extensors of the wrist relax simultaneously.

The conclusion is, that notwithstanding weakness, slowness, rigidity, and tremor, the ordinary muscular components of "voluntary" movement behave physiologically in cases of striatal disease, contrary to the views of not a few writers on the subject.

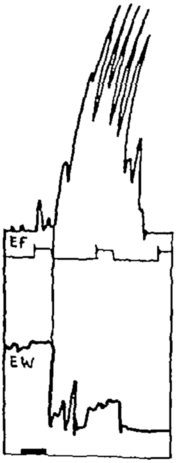
We may now pass to the consideration of another class of movement, which I shall call

MOVEMENTS OF COÖPERATION.

By this expression I wish to signify movements that are auxiliary to other, also "voluntary" movements, preceding or accompanying these as the case may be. Thus when a person seated on a chair is requested to stand up he first of all brings *his feet* in underneath his body, to a sufficient extent, in any case, to place them under, or almost under, his centre of gravity. An essential preliminary to the main movement, the rising up, it aids the latter by enabling it to be *performed with appropriate* ease and may therefore be described as a movement of coöperation. Other writers have called it an "associated movement," an "automatic movement," a "reaction movement," and have declared specifically that such are defective or lost in disease of the corpus striatum. The expressions, "automatic movements" or "automatisms," however, must be avoided, for all degrees exist, from "most automatic" to "least automatic" (i.e., "voluntary"), and no one can say when a movement passes out of the "voluntary" into the "automatic" group. If I have to go down an unknown staircase in the dark, I will gauge the height of the first few steps by feeling with my feet; having estimated it I will probably thereafter proceed more quickly, but I do not pass from a "voluntary" to an "automatic" movement thereby, as if these are two different *sorts* of movement; my stepping movement, a "voluntary" movement, is "variably automatic." Nor is it appropriate to call the movement of drawing the feet under the body a "reaction movement," as Foerster does; in one sense all movements are reaction movements, and the expression becomes meaningless. I shall reserve the term for *another group (to be referred to immediately)* where definite stimuli are used to provoke response. Finally, as we shall see, the expression "associated movement" is equally devoid of specificity unless it is properly restricted in its connotation.

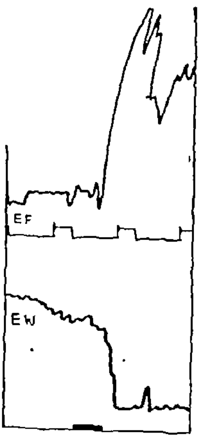
This movement of coöperation, then, I have found to be as a fact present in all cases of Parkinsonism provided the feet are, prior to the assumption of the erect position, placed a little way out from the chair. Applying the test to normal individuals, I have noticed that they can rise up without this auxiliary and preliminary leg flexion as long as the knee angle does not exceed, say, 135°; even then, only with an obvious effort do they "throw themselves" up. Exactly the same principle applies to the Parkinsonian; since he rarely sits with limbs extended, and his customary attitude is one of flexion, his feet are already in a position *de choix* as a rule, *and he can rise* without the auxiliary flexion, but put them out a little and invariably he brings them in to begin with, slowly and unequally as may be. *To say that this and analogous movements are "lost" and to argue therefrom that the corpus striatum is a centre for "automatic" or "associated" movements is, therefore, a fundamental mistake.* Similar remarks apply to the slight outward movement of the feet (extension of the legs) which takes place almost invariably after the normal person has resumed his seat, provided his limbs are close to the chair, or touching it, as he sits down. (This movement, however, is scarcely one of coöperation,

FIG. 15.



Case of severe Parkinson's disease. On the signal ("open the hand") the extensors of the fingers contract and those of the wrist relax simultaneously, in spite of rigidity and tremor.

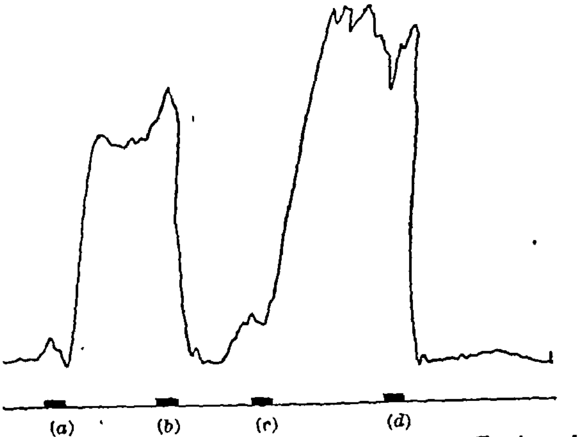
FIG. 10.



Similar case to Fig. 15. Same correct physiological interrelation of extensors of fingers and of wrist. Note how the "voluntary" contraction (synergic) of the extensors of the wrist weakens before the signal (inability to maintain a "voluntary" contraction).

but rather of relaxation, since sitting with limbs flexed at the knees to less than a right angle may become uncomfortable.) The common flexion attitude of the Parkinsonian explains the usual absence of the little outward extension, but in not a few cases (and these not instances of only moderate rigidity) it is readily observable. In one case of bilateral Parkinsonian symptoms (left side more affected than right) the movement constantly occurred on the left side, but never on the other.

FIG. 17.



Normal subject. Combined movement No. II. 3. Tracing of contractions of homolateral erector spinæ. (*a*) Extended arm advanced to horizontal level in front: e.s. contracts; (*b*) arm swept back on same level: e.s. relaxes; (c) arm brought forward again: e.s. contracts; (*d*) arm brought down to side: e.s. relaxes.

Another movement of coöperation to which attention has been given is that accompanying the movement of turning round on a chair. When a person, seated on a chair, is asked to turn—i.e., move his body—round to right or left (hands clasped in the lap), he first of all abducts the leg of the side to which he is to move, then as this auxiliary movement is closing he turns his body, and when the latter movement, similarly, is coming to its end he moves up the other leg in adduction to its fellow. As a rule the head turns simultaneously with the trunk. In the case of Parkinsonian patients the same sequence is commonly observable; occasionally the contralateral leg is slightly adducted before abduction of the homolateral limb, while the head may turn before the trunk, curiously enough. No outfall of subsidiary movement is found to occur, however, in spite of these occasional variations, which, for that matter, sometimes characterise the same act in the normal person.

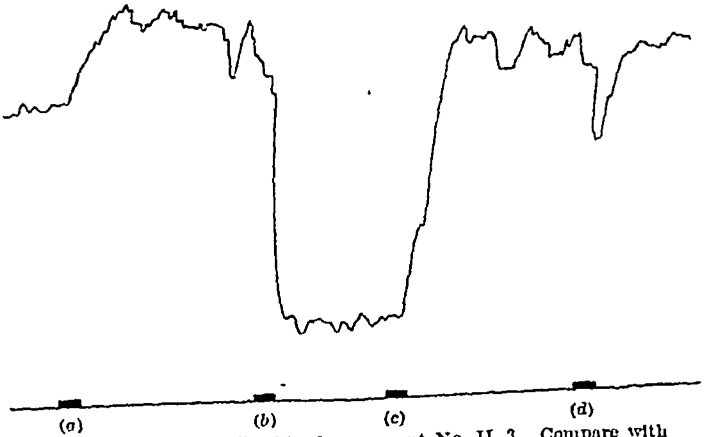
More interesting is the swinging action of the arms in walking, and in a way more important, in view of the fact that it is constantly referred to as an "associated movement," and its supposed "loss" in striatal disease as constantly taken to argue the existence of a physiological centre for "associated movements" in the normal corpus striatum.

"ASSOCIATED" MOVEMENTS.

Few terms are as much in vogue and at the same time as vague in meaning as this is, and its inherent indefiniteness will remain, unless, indeed, each writer will specify the exact sense in which he employs it. In ordinary neurological parlance the term, I take it, is used to denote the involuntary movements of one limb, say one arm or segment of the arm, which may be seen to accompany forceful voluntary movements of its fellow on the other side. Such movements have long been known to be readily elicitable, more particularly in cases of hemiplegia and diplegia—in the former condition usually from the *sound* to the *affected* side, in the latter indifferently from either. The "associated" movement on the second side may, or may not, be a "mirror" movement of that on the first side (to employ the expressions devised by Hughlings Jackson in his descriptions of the variety of epilepsy that bears his name); it often "spreads" on the second side in a way not to be seen on the first. Foerster speaks of them as "the normal [sic] synergias of pyramidal cases"—an unfortunate expression, in view of the fact that they are found in diseased states. It is confusing to find included by Foerster under the same term those muscular actions (extension of the wrist during closure of the fingers, &c.) which we have seen are precisely the normal muscular components of a total single normal movement. Moreover, this author places in the same category of "normal synergias" the spread of movement in hemiplegic cases from one group to another in the *same* limb, as when such a patient cannot flex his forearm without pronating and abducting at the same time, and also the "mass movements" of tetraplegia and spastic paraplegia. No distinction, apparently, is drawn by him between the "associated movements," in his sense, of normal individuals and of hemiplegics, normal and abnormal being classed together; and, finding them both awanting, as he considers, in pallidal cases, he reaches the conclusion already indicated, that the normal corpus striatum is the centre for this type (these types) of movement.

There is here, I consider, a plain error of deduction. Most observers are agreed on the general absence in striatal cases of the above-mentioned and well-known "associated movements" of pyramidal cases, widespreading, tonic, reflex movements which are the result of release of function of lower and older motor mechanisms, and which are *pathological* in the sense that for their appearance a pathological *condition* of the corticospinal system is usual. But it is illegitimate to maintain that the absence in *striatal* disease of the pathological "associated movements" that are proper to the diseased *pyramidal* system argues for their localisation in the basal ganglia. Taking Foerster's own statement, that they are also to be found in the form of "mass movements," we know the latter may be seen in cases of total transverse lesion of the cord—a condition with which the corpus striatum has nothing to do in any direct sense, since it is anatomically severed and as much out of action as in destroying striatal lesions. *The conclusion is unmistakable, that this type of "associated movement" is not effected through the globus pallidus and has no connexion therewith.*

FIG. 18.



Parkinsonian case. Combined movement No. II. 3. Compare with Fig. 17. (For details, see text.)

As for the ordinary "movement synergias" of normal persons—*i.e.*, the normal muscular components of a single movement—the "normal involuntary associated movements of agonistic synergists," in Foerster's elaborate phrase—we have already found them to be typically present in Parkinsonian and other striatal cases, and it is therefore impossible to subscribe to his theory, that they are effected by sensory impulses streaming to the globus pallidus via the optic thalamus from the beginning to the end of "voluntary" movement and *ipso facto* disappear in disease of that part of the basal ganglia. This theory is based on erroneous observation.

Arm-swinging in Walking.

Leaving pathological (pyramidal) "associated movements" and normal components of "voluntary" movement (which ought never to be classed in the group under discussion) on one side, we next ask ourselves whether any other variety remains. And here we may revert to the question of the swinging movements of the arms in walking. My own investigations lead me to suggest they should be regarded rather as "movements of coöperation" in the sense defined above. They are auxiliary movements, practised to enable the individual to maintain balance better during the act. Though normal, they are in no respect inevitable, for the simple reason that anyone can walk with his hands clasped behind his back, or with his arms held stiffly in front or in any other artificial fashion. He will at once, however, be conscious of the lack of ease in walking thus, and will revert with relief to the normal swinging. At the other extreme is the powerful use made of the swinging arms by expert athletes in walking races, when the upper limbs can be seen to be voluntarily utilised by exaggerated sweeping movements across the chest with a view to facilitating progress. I cannot assent, therefore, to the opinion either that this arm movement is a constant normal "associated movement," or that it is purely "automatic."

Of its common reduction or cessation in Parkinsonian cases let me admit at once there can be no question. If the normal individual is carefully watched, the movement, I find, largely consists of moderate flexion at the elbow, with but slight advance of the limb at the shoulder. On the whole, the arm moves through a wider range in front of the mid-axillary line than behind it. Now if a Parkinsonian be watched as he walks with body stripped, absence of any forward movement at the shoulder will at once claim the observer's attention, and as a slight advance at the proximal end of the limb would, of course, result in a materially wider excursion at the distal end, its failure to occur will affect the whole limb. In a fair number of instances, however, some flexion at the elbow takes place. In other, asymmetrical, examples of the disease the less affected arm will move with some freedom as compared with the worse; in unilateral cases the sound arm will move normally enough, but this class of case sometimes presents unusual and interesting features. A moment's thought will remind us that the normal arm is moving with the impeded leg, and I find on observation of several such examples that the movement of the sound upper limb is made to correspond with and in a sense to compensate for the defect of the opposite lower limb. Thus in one case (largely right-sided) the left arm was always advanced to a distinctly *greater* extent than usual, and this corresponded strictly to a slower advancement of the weak right leg. In another case (also right-sided), the normal left arm was never quite at the side, but was held in advance continuously and made a swinging movement through a rather reduced range in this advanced position. In unilateral instances the movement of the sound arm is "variably automatic."

It is instructive to note how frequently intelligent patients are aware of this imperfection of arm-swinging during their walk, even at a comparatively early stage, but if they are asked deliberately to swing the arms—"as they should do"—curious effects may result. For example, while some will manage for a time to move the arms alternately and appropriately, the movement will have a somewhat unnatural look; others, again, as I have seen more than once, move the arms forward and backward together in a ridiculous way; another patient (unilateral left-sided case), told to swing the left arm "properly" as she walked, did so only at the expense of the right arm, saying, "If I try to swing my left arm my right arm stops swinging." Patients, too, who when given a similar request hold both arms forward with a minimum of swing have been observed. In one case the patient made the spontaneous remark that the left arm (affected side) "felt different"; "in walking I feel as if the left arm has no weight, as if it were hanging by a thread." Another made the candid and illuminating observation: "It is easier not to swing my arms."

The explanation of this frequent though not universal phenomenon is to be found by reference to more than one consideration. Undoubtedly the factor of proximal rigidity plays a significant rôle, as is immediately evident when the patient walks stripped; involuntary contraction of deltoid and upper arm muscles keeps them relatively tense, and no alternating "play" between anterior and posterior groups is observable. I have not yet seen a case of reduction of this specific arm movement in which those muscles could be said to exhibit normal muscle tone. The hemiplegic patient does not swing his rigid arm. The matter of muscular "effort," again, cannot be ignored, and the same remarks are applicable in this respect as have been offered above, apropos of the Parkinsonian's general immobility. Largely "automatic" though the arm-swinging be, it encounters resistance; hence not to do it is "easier." In forcing the movement deliberately the Parkinsonian encounters the same difficulty as with any of his "voluntary" movements, and the result is one or other of the various anomalies already enumerated. Nor must it be forgotten, as before-mentioned, that arm movements are not absolutely essential in the walking act, and since the patient can as a fact walk without their aid, the faint element of conscious volition which should assist in stimulating them to action is ignored.

My conclusion, therefore, is to the effect that, this arm-swinging being neither constant, essential, nor purely "automatic," and partaking more of the nature of movements of coöperation or auxiliary movements than of involuntary or reflex associated movements, its reduction or absence in cases of striatal disease cannot be regarded as in any way supporting a theory of the localisation of "associated movements" or of "automatisms" in the corpus striatum.

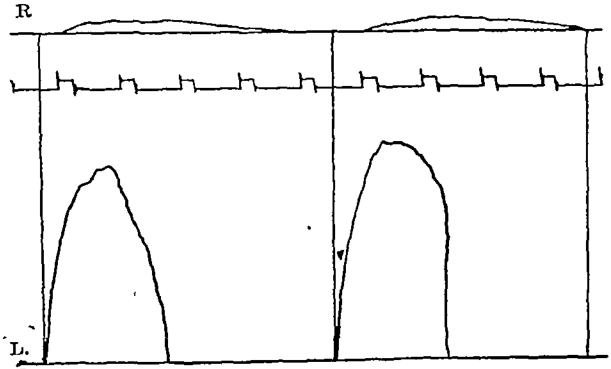
PRESENCE OF CERTAIN "ASSOCIATED MOVEMENTS" IN STRIATAL DISEASE.

Finally, under this heading, I wish to direct attention to the frequent or almost constant occurrence, mainly in unilateral cases of Parkinsonism and allied conditions, of a variety of "associated movement" from the *affected* to the *sound* side, but not, as a rule, vice versa. Many times have I had occasion to observe how in the performance of individual "voluntary" movements with the affected arm, hand, or fingers (especially in the case of the latter two) an identical, "mirror" movement is executed on the sound side, smaller in range as a rule and usually at least as slow as the other—sometimes, in fact, more prolonged. For instance, abduction of the little finger on the weak side is accompanied by the same movement of the normal finger, extension of the wrist on the affected side by extension of the wrist on the other, and so on. In ordinary bilateral cases these phenomena are very often awanting, but should one side be more affected than the other they are commonly still to be seen, always from the more weak to the less weak side. So much is this the case that the observer can thus sometimes decide, by a rapid and simple test, which of the two sides is the more involved.

The tracing reproduced in Fig. 19, taken from a unilateral case, shows how flexion of the forefinger of the affected arm (below), relatively good if somewhat tremulous, is accompanied by a fine flexion of the forefinger of the normal hand, beginning a fraction of a second later, considerably more restricted in range, and, in this instance, continuing a second or two after the movement of the first side has ceased. (Kinematograph films that I have had taken give more striking examples of the crossed muscular action.)

Movements of this character have been described in another connexion by Pierre Marie and Foix as "syncinésies d'imitation," and are stated to occur indifferently from either side in cases of hemichorea and hemiathetosis. The peculiarity here remarked is their occurrence mainly *from* the *affected*, or more affected, *to* the *sound*, or less affected, side in cases of striatal disease, which, according to the usual views, are characterised by absence of all "associated movements." Comment has already been made on the loose way in which this expression is employed, so much so that it is in danger of becoming valueless; but while the phenomena just described differ in some respects from the familiar involuntary "associated movements" of pyramidal affections they clearly exhibit in point of fact the element of "association" and deserve attention. They can be, and often are, inhibited, especially if the subject becomes aware that the examiner's attention is directed to the crossed movement rather than to the requested movement of the weak limb; but they are not found to occur in normal people, where individualisation of movement is perfectly developed, and I do not believe, as do Marie and Foix, in the existence of a "normal tendency" to imitation by one side of the movements of the other. Simple though the movement is, a satisfactory explanation is not easily found. The conjecture might be hazarded that the peculiar unilaterality, the occurrence mainly on the unaffected, or less affected, side, points to an "overflow" of the innervation current at a low (cord) level to the corresponding motor centre of the other side, conceivably because of the relative "block" encountered by it in the (affected) muscle units to which it is directed; this tendency to cross-innervation is readily inhibitable from the cortex. Since no such obstacle is met on the healthy side, there is no tendency when *it* is innervated for the current to cross to the affected side. I do not think that any explanation based on bilateral representation of individual movements in the cortical motor centres applies here; we cannot say it is in any way customary for such corresponding muscular groups to be innervated simultaneously and identically, at least in the case of the muscles of the fingers and hands, where marked individualisation is the rule.

FIG. 19.



Unilateral Parkinsonian case. "Associated movement" of right (normal) index finger during "voluntary" flexion of left forefinger (affected side). The associated contraction is much less in degree but lasts longer.

In further contradiction of the general opinion as to loss of "associated movements" in striatal affections, a word may be said on a peculiar variety of synkinesis which I first noticed a number of years ago in cases of paralysis agitans and which has been repeatedly observed in patients suffering from the diseases of this group, while it is according to my investigations of but rare occurrence in normal persons. When the Parkinsonian is asked to make a series of successive right and left conjugate deviating movements of the eyeballs (the head being kept steady) he very frequently blinks his eyelids as the eyes pass from one extreme lateral position to the other. The blinking movement, of which he appears to be unaware, is sometimes quick, sometimes slow and deliberate. In more than one case a quick double eyelid flicker has been distinctly and repeatedly observed. This transient complete or incomplete eyelid closure is the more noteworthy in that Parkinsonians as a rule are conspicuous for the poverty of blinking movements, as has been made the subject of previous allusion. Now normal subjects, who blink easily and readily, do not show this particular "associated movement" to anything like the same extent, though I do not say it is never seen. So high a proportion of Parkinsonian patients exhibit it that I have come to regard it as more typical of that condition than of any other. Yet no explanation of this eye-blinking associated movement that I can think of can be said to be satisfactory, and for the present I am content to note its existence.† (A kinematographic film of this "associated movement" was exhibited.)

Summing up our clinical data and our deductions therefrom, we are justified in the *general conclusion, that striatal disease is not characterised by complete outfall of "associated movements"; we naturally do not expect the special variety discoverable in pyramidal affections to be present in extrapyramidal disease and therefore cannot in any sense describe it as "lost"; other varieties are actually found in striatal maladies and not in normal subjects; others still have been erroneously included in this class of movement and any argument based on their reduction or absence is thereby vitiated.*

MOVEMENTS OF REACTION AND DEFENCE.

In this category are comprehended movements in response to definite stimuli and those performed by way of protection or defence from some nocuous excitation. Such motor responses are frequently designated "reflex movements," but this term is undesirable. In the intact organism an immediate response to a nocuous stimulation is called "reflex," as when the eyes are closed on the flash of a bright light (in any flashlight group photograph a percentage of the "sitters" are seen to have their eyes shut). Yet in numerous instances a conscious element cannot be said to be excluded. The hand is moved with urgency from the contact of a hot surface, but the sensory impulse must reach the cortex first, there to awaken a conscious sensation of heat. Otherwise expressed, the "reflex" arcs extend to the cortical level, *and if so it is preferable they should* be distinguished as a class from reflexes confined to lower physiological levels, however analogous their mechanism.

The general statement is frequently made by those concerned to defend current conceptions of striatal function that in striatal disease all movements of reaction and of defence ("automatisms") are impaired or lost, whence we may infer the tacit assumption is drawn either that consciousness enters into striatal activity or that striatal "automatisms" blend in some undefined way with higher (cortical) coördinated movements. My own observations in this respect also lend no countenance to the theory of striatal function erected thereon.

---

† I have under my care in hospital at present a remarkable case of postencephalitic Parkinsonism in a young woman. She exhibits extremely slow, incomplete, and punctuate lateral deviation of eyes to right and left, but she has discovered for herself that if she lets her eyelids droop, or shuts the eyes, as she deviates the eyeballs conjugately from side to side, their movement becomes at once quicker and more complete.

When testing for the class of movements now under review it is imperative the subject should have no cognisance of what is about to be tried out. I devised a series of chair-tilting tests in which the patient's chair was abruptly moved in one direction or another by an assistant behind him, while the observer was seated in front. The degree to which conscious knowledge of the tests to be made interferes with the reactions is sufficiently indicated by the remark of a patient whose responses became less and less as the examination proceeded and who, when comment was made thereon, said, "I know now you won't really let me fall off." Cases of severe generalised Parkinsonism were selected for the purpose, the patient being seated on a chair with hands on lap and then tilted abruptly forwards or backwards or to one or other side. A single series may be briefly summarised to illustrate results. In this instance the case was that of a woman of 28, suffering from the postencephalitic variety.

(1) Tilted to L. The left leg was at once abducted, the left arm extended, abducted away from the trunk, and directed towards the corner of a table which stood near. As further falling to the left continued, the right arm was in turn brought across and directed also to the table. There was no movement of the right leg.

(2) Tilted to R. The right arm was immediately extended and abducted and the fingers extended as if to save from the floor. The left leg was notably abducted, extended, and elevated, as if to counterbalance the right lateral deviation. No movement was observed in left arm or right leg.

(3) Tilted backwards. Both arms were at once thrown out in extension in front, both legs were abducted, and slightly extended at the knees.

Pushing tests were utilised in the same case, the subject having the eyes closed to obviate foreknowledge.

(1) Sudden push backwards. Both arms were thrown out in front in full extension.

(2) Sudden push to L. and R. respectively. In each instance there was marked quick abduction of the ipsilateral leg, with slight abduction of the contralateral arm.

All sorts of variations have been seen in different subjects, and in some the reactions have been considerably restricted as compared with the above. Thus in the case of a man of 27 (postencephalitic form) in whom the left side was distinctly more affected that the right, chair-tilting to the *left* evoked abduction of the *right* leg, then feeble abduction of the left, while the edge of the chair was gripped with the right hand; whereas, on tilting to the *right* only the *right* leg was abducted, and no movement of the left limbs was detected. On sudden pulsion backwards the same individual's reaction was confined to slight but definite advancing of the right arm. Another patient whose responses to these tests seemed peculiarly meagre (a girl of quick intelligence, she early realised that she would not be allowed to hurt herself), was asked to bend backwards as far as she could, on the pretence of examination of the back muscles. The supporting hands were suddenly removed, when at once both her arms were thrown forward and she tried to catch hold of the assistant standing in front.

In view of these findings, which might be readily amplified, we shall be careful in our interpretation of the seeming absence of reaction among Parkinsonians to peripheral stimuli of differing sorts. Foerster, for example, says they exhibit no movements of reaction to irritation from flies, but neither do the moribund, nor the profoundly asthenic from serious illness, nor those in whose case for other physical reasons the reaction requires an effort. "It is easier not to." Indifference and apathy led to similar absence of reaction on the part of the long-suffering soldier on the Gallipoli Peninsula. In short, so manifold are the factors leading to this apparent poverty of reaction movements, and so clearly is there resident in them a cortical, because conscious, element, that their ascription to striatal function can be dismissed as a conjecture lacking inherent probability no less than any clinical support.

The question can be further probed by resort to the familiar tests for defence-reactions to stimuli along the sense avenues of touch, sight, hearing, &c. With the proviso that the subject be unaware of what is to be examined for, the nostril, ear, or throat can be tickled, visual or auditory excitations of a sufficiently "threatening" or "alarming" character utilised, or painful cutaneous stimuli employed, and in practically all instances a response or reaction will be evoked, proving the inaccuracy of the general statement already referred to. If the hand be suddenly passed across in front of the patient's eyes with a threatening gesture he blinks and may withdraw the head; at the unexpected bursting of an air-filled paper bag he also blinks; when the auditory meatus, or the nostril, is tickled with a paper "spill" the head is inclined away, and so forth. Only in exceptional instances do such reactions fail. Thus I have seen tears running from the eyes of a Parkinsonian when his anterior nares were tickled, yet no outward reaction was otherwise noticeable: another patient blinked his eyes when a feather entered his external auditory meatus but the head did not move away. I have convinced myself, further, of the general inaccuracy of the view according to which patients with paralysis agitans furnish no visible evidence of a reaction to painful cutaneous stimuli; on the contrary, withdrawal from the nocuous excitation in my experience rarely fails. If the fauces are irritated with a paper "spill" moderate "gagging," with movement of eyes and mouth, results more or less regularly.

In seeking an explanation for the occasional absence, and less infrequent reduction, of movements of reaction and defence we do not require, as hinted above, to go past the factors already enumerated, in particular, that of awareness, the action of which has been sufficiently demonstrated. I shall not be misunderstood, I hope, when I say also that with certain patients of the hospital class the rôle played during examination by a "superior" is so passive as of itself to tend to reduce external reactions to a minimum. Many patients by no means as generally immobile as the Parkinsonian will submit to repeated pin-pricking in sensory tests with stoical calm, and the same is true of ordinary sole-stimulation in investigating the plantar reflex. As a persistent background in rigid cases is the muscular state, which of itself, as we have several times had occasion to remark, contributes to reduction of facile reactions, to an extent, indeed, that cannot be ignored.

MOVEMENTS OF EXPRESSION.

Hitherto our concern has been exclusively with the so-called "voluntary" motor system and its activities when there is reason to believe the striatal system is largely out of action, but I must now refer to another class of movement which, commonly called "involuntary," is nevertheless more conveniently discussed at this stage than later, when we come to examine chorea, tremor, and athetosis.

Scarcely any greater clinical contrast can be imagined than between the mobile and facile emotional expressions of the Sydenham's choreic and the "starched" and "fixed" facies of the Parkinsonian. In the latter it is not an absence of all expression but rather a fixity of expression, a lack of ease in passing from one expression to another, a lingering exteriorisation of emotion, with which we have to deal.

Though not specifically alluded to in the classical monograph of James Parkinson, the Parkinsonian "mask" is a classic symptom, not requiring elaboration by any writer of to-day. I may state briefly that patients can and do both laugh and cry, that their expressions frequently exhibit an exaggeration amounting almost to a *rire* or *pleurer spasmodique*, and that in unilateral cases the affected side moves more slowly than the other in the expanding or unfolding of its expression, but tends to maintain this after the other has become normal again. A distinction is to be drawn, none the less, between the true *rire et pleurer spasmodiques* of the pseudobulbar and the exaggerated facial emotional expression of the Parkinsonian, in that the "convulsive" element of the former is awanting in the latter instance, in which also there is far less implication of the respiratory part of the mechanism for the display of emotion, while the quality of the laugh is often inferior. As a postencephalitic patient remarked, "I used to have a ringing laugh, but now I make a silly noise." It is not that, as in pseudobulbars, double hemiplegics, cases of disseminated sclerosis, and so on, the facio-respiratory emotional apparatus is "released" into exaggerated action, but that the apparatus itself, an "involuntary" mechanism, is subject to the same muscular disabilities, so to speak, as have been described in the case of the "voluntary" motor system. For we are dealing, as is immediately understandable, with skeletal, not with unstriped, muscles; the problem pertains to the "involuntary" use of a "voluntary" musculature. Now there is no good reason to suppose the "inward" or central (psychical) part of the mechanism has undergone a change; the Parkinsonian is no less conscious than the normal person of the stimulus that conduces to laughter or awakens tears; hence such abnormalities as he shows must be set down, inter alia, to the existing hypertonic condition of the muscles involved, that rigidity which seriously interferes with facility in or versatility of muscular play. In a study of the subject published a year or two ago attention was specifically drawn to impairment of the expression of the emotions from organic lesions, and allusion was made to alterations consequent on paresed, rigid, ataxic, and other states of the facio-respiratory apparatus; among these, Parkinsonian rigidity is to be included. The important point that I wish to make at present is that *the mimic or expressional movements under consideration are "most automatic" or "least voluntary," but they nevertheless reveal disorder of function as definitely as do so-called "voluntary" movements.* (I am in no sense dealing here with the varying respiratory disturbances that have been observed within the last few years among the sequelæ of epidemic encephalitis.) It is the more necessary to stress this point in view of the distinction which some have attempted to prove exists between "voluntary" and "involuntary" use of the musculature in paralysis agitans, the former exhibiting defects of function and the latter not. The evidence now adduced lends no support to this attempted differentiation. (See also below.)

Poverty or lack of movements of the limbs in gesture and expression is, of course, a mere corollary of what we have learned as to the "Bewegungsarmut" in general. The "mimische Starre" or mimic fixity of the Parkinsonian, inclusive both of facies and of limbs, is a consequence of more than one factor, of factors already sufficiently discussed, and is, in my opinion, erroneously described as a mimic "paralysis," for reasons given above. Hence, when Binswanger and others argue as it were backwards from the symptomatological to the physiological, and place in the corpus striatum a "higher coördination centre for unconscious mimic and gesture play," they misinterpret the clinical phenomena in the first instance and overlook other significant clinico-anatomical data in the second. For, in the article already alluded to on "Pathological Laughing and Crying," I have brought forward evidence to suggest that there are corticifugal (non-pyramidal) paths from the frontal lobes via the optic thalamus to the facio-respiratory centres in the pons and medulla, and that these are the routes taken by emotional impulses to modify the facio-respiratory synkinesis in the direction either of laughter or the reverse; genuine absence of emotional movement, genuine emotional palsy, occurs from lesions situated *ex hypothesi* anywhere on these tracts, from the cortex to at least as low as the pons. *No theory attributing emotional disorders to disease of the corpus striatum alone can be accepted, since it fails to include a number of germane clinical and pathological facts.*

Muscle Tone.

By muscle tone is commonly understood that condition of contraction of a resting muscle which exists without "voluntary" innervation and which holds the limb in a given position. It also exists when the limb is passively supported, for the muscles do not "sag" or hang flaccid. When, further, the limb is passively moved a mild resistance to the displacement is encountered; when it is held and shaken the segments concerned exhibit no flail-like swinging as do those of a limb considered to be hypotonic or atonic. Thus muscle tone gives a shape to muscles, and is in evidence both in resting (static) and moving (kinetic) states of the musculature. According to the researches of Sir Charles Sherrington, tone is in reality postural contraction, that is to say, it is a moderate contraction of muscle-fibres effected reflexly by sensory excitations arising in peripheral end-organs, substantially those of the muscles themselves. In virtue of this reflex contraction, a muscle will adapt itself to the maintenance of any posture, whether the fibres are in fact in a shorter or longer anatomical state; the property of adjustment of length of fibre, and of exercise of contracting power whatever the length, he described as "plasticity," whence has arisen the use of the term "plastic tone," to be referred to immediately. All clinicians agree that lesions interrupting the proprioceptive reflex arc underlying muscle tone confirm the conception by producing, as a fact, loss of tone.

The point next arises whether this muscular function of reflex contraction is subserved by all or by a special group of striated muscle-fibres. I can now only refer in the very briefest fashion to a hypothesis that has gradually developed more particularly during the last decade, to the effect that all fibres partake in postural tone but that (as the form of the hypothesis due especially to Hunter has it) there is a subdivision of labour, so to say; some fibres, said to be histologically recognisable, are innervated by the motor or efferent limb of the proprioceptive arc alluded to above—i.e., by the somatic nervous system—and contract reflexly during change of posture; they are considered to be responsible for what has been called "contractile tone," because they contract in response to appropriate stimuli. Other fibres, stated to be histologically distinguishable, are innervated by the sympathetic nervous system, but they are not contractile; their length is supposed to be *passively* altered during the activity of neighbouring contractile fibres (the first group); and their postulated function is to remain at a given fixed length once movement of the others has ceased, and thus to aid or support the maintenance of posture determined otherwise. They are said to be responsible for "plastic tone"—i.e., the element in postural tone concerned with the adaptation of a muscle to the new posture assumed after movement. "Plastic tone" and "contractile tone" together make up "postural tone."

While Hunter asserts the sympathetically innervated fibres for "plastic tone" are *non-contractile*, he makes no reference, as far as I have seen, to the old Vulpian's phenomenon (1862), recently reinvestigated by Langworthy. The latter finds that stimulation of the lingual nerve (containing bulbar autonomic fibres) leads to slow wavy contractions of the tongue muscles after complete degeneration of the hypoglossal nerve-endings by previous section, and is inclined, therefore, to believe in the possibility of *contraction* via the sympathetic nervous system.

Be this as it may, the identity of tone and of contraction cannot be seriously questioned. For physiological proof of this statement the clinician has to turn to recent work with the string galvanometer (personally I have had no opportunity of prosecuting such researches and must rely in this respect on the investigations of others). Very briefly, it has been shown by exact methods that an action-current exists in normal muscle at rest, that there is no notable difference in the action-current as between active ("voluntary") movement and passive movement, that the action-current of normal muscle differs from that of rigid and spastic muscles only quantitatively, not qualitatively. Further, the curves of the current during passive movement of a hypertonic muscle are the same as those of strong "voluntary" innervation; no qualitative distinction is to be *found between the action-currents* (during both active and passive movement) of Parkinsonians and of hemiplegics; or between the action-currents of the same conditions when the muscles are at rest. In respect of this latter point, the curves both in hemiplegia and in paralysis agitans are more marked than in resting normal muscle, and in paralysis agitans rather more than in the pyramidal affection (Hansen, Hoffmann, von Weizsäcker, Wachholder, Mann and Schleier, and others). The general conclusions are, that tone and "active" innervation are analogous phenomena, that only quantitative differences are to be detected between the action-currents of "voluntary" innervation and of hypertonic states of pyramidal and extrapyramidal origin, that the muscle tone exhibited on passive movement in these morbid conditions (resistance to stretching) is entirely analogous to the so-called tetanic innervation of "voluntary" contraction. A number of years ago Lewandowsky maintained that "tonus is nothing else than the observation of a particular attitude for which the same laws hold good as for the carrying out of a movement."

What actually happens when "volition" innervates a resting tonic muscle is probably that it strengthens the existing ("involuntary" or reflexly produced) contraction, as is suggested by a significant experiment of Graham Brown, to which attention was drawn in my paper on "The Old Motor System and the New." According to Holmes, tone "fuses with muscular contractions otherwise aroused [e.g., by 'volition'], reinforcing them, making them more tonic." The reader is referred again to the tracing obtained from the erector spinæ of a Parkinsonian during the combined arm movement described above (Fig. 18). From this record it is clearly established that the existing "involuntary" or postural contraction of that muscle (its tone—in this instance, hypertonia) is *reinforced* by the "volitional" element of active contraction, so that the curve rises still further, if somewhat slowly. I attach importance to this demonstration, since Hunter asserts (without, seemingly, offering evidence in support) that "in voluntary movement postural tone, made up of a contractile and a plastic component, is first *inhibited*" (italics mine); according to my observations this is incorrect.

The difficulties of gauging tone by ordinary clinical methods are considerable; we estimate the "*feel*" of the muscles by reference to our own subjective standard based on knowledge derived from palpation of many presumably normal muscles; we observe attitude; we impress a passive movement on the muscle concerned; we calculate its "stretchability." From what has been already shown at various previous stages in our discussion, the difficulty is increased by inability to separate "voluntary" from "involuntary" contraction by objective clinical methods; by the fact that the conscious patient will often "unintentionally" coöperate during passive movement, so-called; by the varying degree of "automatism" in any frequent movement; by recognition of the truth that not all attitudes are "involuntary." In view of the physiological data obtained by the string-galvanometer method, moreover, we are really asking ourselves to estimate merely *quantitative* differences, a task of obvious arduousness. While major degrees of hypo- or hyper-tonia do not, as a rule, offer any difficulty, minor degrees escape us clinically, and the passing from a reflexly determined contraction to an incipient "voluntary" contraction (without displacement) is for practical purposes not determinable. Conversely, we lack methods for gauging with exactitude at what point a postural tone reaction fixes or stabilises a movement begun by "volition."

A further introductory word is necessary in respect of the recent tendency to differentiate somewhat rigorously and schematically movement from posture, and kinetic from static muscular contractions. Speaking generally, "volition" is taken to imply *movement*, and reflex action, *posture*, yet the inapplicability of the generalisation must be plain to the reader; posture is often maintained "voluntarily," and much reflex action is of a definite kinetic character. Movement is in reality a series of changes of posture, and Sherrington has stated that the distinction between reflexes of posture and reflexes of movement is not clear-cut. That two entirely separable mechanisms should be responsible for posture and movement respectively is *primâ facie* improbable, in view of this statement of Sherrington's for reflex action, and of the known phenomena of "voluntary" action. Cogent arguments against this differentiation have recently been urged by Bard, with whose contentions I find myself in substantial agreement.

MUSCLE TONE IN STRIATAL DISEASE.

Study of an average case of Parkinsonism or of progressive lenticular degeneration, even by the comparatively crude clinical methods to which we have resort, at once reveals the presence of increase of muscle tone. The muscles stand out and have shape; where their tendons are visible these are salient; to the palpating finger they are firm and *tense*; they offer definite resistance to passive extension, and more force is required to effect passive displacement. Further, such patients exhibit "at rest" an attitude, indicative of access of tone in certain groups.

Distribution of Muscle Hypertonia.

The bellying of the skeletal musculature is more or less universal, but is more recognisable, on the whole, in those groups whose contraction underlies the maintenance of specific Parkinsonian attitudes (sternomastoids, erectores spinæ, deltoid, biceps brachii, *supinator longus*, wrist extensors, long finger flexors, interossei, thenar and hypothenar groups, knee flexors, tibialis anticus, &c.). Rigidity—i.e., resistance to passive movement—is so widespread that it may be described as general, though it is more pronounced at the larger joints, being presumably there a question simply of muscle mass. Even when a limb or limb segment is passively put in such a position as to relax muscles as far as possible hypertonia is evident. In the recumbent posture the sternomastoids do not relax. When any joint of any limb is passively displaced resistance is encountered whatever the direction of the displacement. We have already had evidence pointing to the implication even of quite small muscles—e.g., those of the larynx—in this generalised rigidity, and it is doubtful whether the external ocular muscles completely escape. In the result, the patient can often be passively moved *en bloc*; if the head be rocked about the trunk follows its every move, and so on. A degree of rigidity equal to that of the severest pyramidal cases is probably attained but seldom (unless, indeed, the stage of myogenic contracture has been reached); it is not so easy to pull a Parkinsonian about by one leg, the other following, as it is in the case of a pronounced spastic paraplegia.

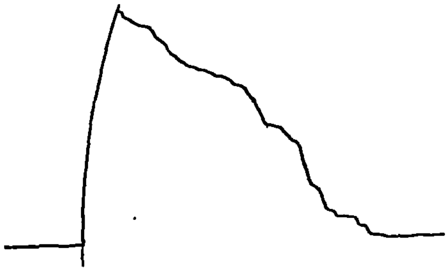
Characters of the Muscular Hypertonia.

When the hypertonic muscle of the striatal case is passively stretched resistance is felt from beginning to end of the movement; in the milder cases the origin and insertion points of the muscle to be tested should first be approximated and the passive stretching should be comparatively fast. If the stretching is quite slow little or no resistance may be demonstrable. The explanation doubtless is to be sought in the stimulation of proprioceptive end-organs by the abruptness of the initial passive movement, with consequent reflex increase of the muscular contraction and therefore of resistance. Strümpell is of the opinion that striatal rigidity remains more or less the same whether the passive movement be slow or abrupt, gentle or powerful, but my observations do not confirm this view, nor do I consider it can be applied as a clinical method of distinguishing pyramidal from extrapyramidal rigidity. Figs. 20 and 21 are two records from the same muscle (biceps brachii) of an advanced postencephalitic Parkinsonian; in the former of these the muscle (already contracted) was passively and slowly extended in the course of three seconds; in the latter, the same movement was made abruptly and strongly, occupying not more than a quarter or a third of a second, and the characteristic "cogwheel" character of the resistance stands out with greater clearness in it than in the other.

The statement has already been made that the rigidity is practically universal in striatal cases; in the various divisions of the musculature it varies in degree only. It is found, therefore, in muscle groups which in pyramidal affections exhibit little or none of such hypertonia (see also below). Like one or two other phenomena of postencephalitic Parkinsonism, it may show a curious reversibility, fluctuating from time to time in an unexpected degree—a character not met with to the same extent in pyramidal cases. In deep sleep careful observations by my house physicians have proved it to be markedly reducible, frequently if not constantly. Cutaneous sensory stimuli exercise no apparent effect on its character; it is not temporarily "broken down" thereby, in contradistinction to what obtains in pyramidal disease. It seems to be aggravated by cold and reduced by warmth.

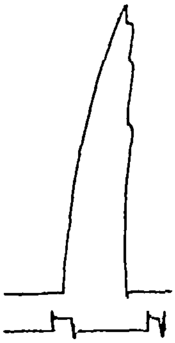
In spite of the plausibility of the view that muscle rigidity is mainly responsible for impairment of "voluntary" movement, I am not able to satisfy myself there is always a specific connexion between the two. I have not found that movement is always braked by the existing rigidity and brought to a standstill more or less completely and soon, as Foerster states. If the reader will refer back to the observations described in a previous lecture in this series he will gather that peripheral rigidity is only one, and that not necessarily the most important, of the factors producing limitation of range and power, and constituting "paresis," in respect of "voluntary" contraction. I have demonstrated the physiological normality of the mechanism of volitional innervation in regard to its muscular components, concomitant rigidity notwithstanding. We have had evidence to show that "voluntary" muscular contraction blends with existing tone and is rendered more tonic. Were the rigidity really to function as a constant and immediate brake on "volition" a difference might be expected between the curve of a rigid muscle under passive and active extension respectively, since in the latter the extension is part of a "volitional" action. By physiological (action-current) methods no such difference is discoverable. With cruder clinical technique the arm of a patient with severe paralysis agitans was fixed so as to prevent any subsidiary movement; the biceps brachii was in the first instance passively stretched, the time taken being roughly two seconds; another tracing gave active ("voluntary") extension of the same muscle, in the same time, and under the same conditions, and no distinction could be found. However, single instances must not be unduly stressed, and from this illustration, further, the inference is not to be drawn that hypertonia does not impede passive movement, for the reverse is the case. In analysis of the actual hindrance encountered by "volition" in the motor periphery due weight must be placed on the state of the antagonists, as we shall shortly see. This is of greater significance than hypertonia of the prime movers, though one might conceive so exaggerated a condition of agonist hypertonia that the incoming current of "volitional" innervation produces little or no evident result. No such case, as a fact, has as yet come under my notice.

FIG. 20.



Parkinsonism. Slow passive stretching of biceps brachii.

FIG. 21.



Same case as Fig. 20. Quick passive stretching of biceps brachii; "cog-wheel" phenomenon well seen.

A further word is necessary in this connexion as to the type of movement in which abnormal states of the musculature will produce its effect. From the observations made in the course of testing various kinds of movement, as described previously, the element of rigidity has been seen to contribute to the general imperfection in all; that is to say, it hampers movements of a "most automatic" kind no less than those that are "least automatic," as might, indeed, be expected. If there is a persisting background of agonist-antagonist rigidity, "volitional" innervation of a given muscular unit cannot differ from "automatic" innervation, since both use the final common path in a Sherringtonian sense. I have not found, therefore, in working on this class of case, that any support of a clinical kind is furnished to the contention of Kousnetzov, who says that in extrapyramidal hypertonia "it is above all the voluntary movements that are affected."

TREATMENT OF PHTHISIS WITH SANOCRYSIN.

BY KNUD FABER,
PROFESSOR OF CLINICAL MEDICINE, UNIVERSITY OF COPENHAGEN

WHEN we began to use sanocrysin about six months ago in the University Clinic in Copenhagen for the treatment of some cases of chronic lung tuberculosis we were prepared to see serious consequences follow the sanocrysin injections in severe cases in view of the already published experiences. In the first few weeks we also had cases in which the reactions caused by the treatment could not be controlled, so that the patient succumbed before he otherwise would have done. We fairly quickly discovered, however, what the special dangers were and how they could be avoided, and in the last five months we have had no disasters of this kind. The treatment has thus been freed from the drawback which at first attended it, and we are now in a position to judge more soberly the therapeutic results we have attained during these months.

Dangers of the Treatment and How to Avoid Them.

Before giving an account of these results it is appropriate to discuss in rather more detail the dangers which may accompany the treatment. They are fully dealt with by Secher and Würtzen in the book, "Chemotherapy of Tuberculosis."[1] What is of special interest now is to realise that they can usually be avoided. It is the present purpose to discuss these from a purely clinical standpoint without entering into the still hypothetical explanations of how they arise. Indeed, the whole question of the mode of action of chemotherapeutic substances is still far from being cleared up, and the same undoubtedly applies also to this new chemotherapeutic specific drug.

---

[1] THE LANCET, 1925, i., 239, 555.

The greatest risk is the occurrence of the acute state of collapse described by Mollgaard as shock. It is characterised by a marked fall in temperature, the patient becoming pale, sweating, and showing signs of heart weakness with a very rapid and small pulse, and the gradual onset of cyanosis and other signs of cardiac failure. This is the condition which is combated in a very striking manner by the intravenous injection of antitoxic serum.

Our experience is that signs of shock are most likely to occur when an injection of sanocrysin is given while the patient still shows a febrile reaction from a previous injection. As a rule, a long febrile reaction, lasting from one to two weeks, where the temperature rises and falls fairly steadily, ensues after one or two sanocrysin injections. This reaction must be allowed to pass away before a fresh injection is given, and one must watch when it begins. By giving an injection too early, just when the fever is starting, the patient is exposed to the danger of shock, and even if this does not occur the reaction is increased in strength, so that it is more protracted and violent in every respect than it would otherwise be.

The same thing may happen if the patient is febrile before the first sanocrysin injection is given. If the usual dose is administered in such a case there is a risk of shock. One must either wait until the fever has disappeared or begin with a much smaller dose. In a case of acute tuberculous lobar pneumonia that came in with a temperature of over 40° C., we observed the occurrence of shock after a dose of only 20 cg. If one recognises these facts, shock can presumably be prevented, or at any rate, one will only get incipient shock, which can easily be controlled by an intravenous injection of antitoxic serum.

In order to avoid interfering with the long febrile reaction it is essential to bear in mind that in some cases it does not start before two to four days after the second sanocrysin injection, while in other cases it may appear after a single injection of only ½ g. In both cases a too early injection of another dose may be dangerous.

The danger resulting from the first injections of sanocrysin following too rapidly upon one another may, however, show itself in another manner than by the occurrence of shock. The fever reaction may become too severe and rise to a fatal hyperpyrexia. When we were first trying sanocrysin, in one case where three injections were given with only one day's interval, the temperature began to rise and without intermission reached 42° C., after which violent heart attacks and intestinal hæmorrhage occurred and death supervened.

From these facts it appears that the danger chiefly consists in the injections following too rapidly upon one another, with consequent accumulation. The same conditions also seem to reinforce the third variety of intoxication phenomena which in the form of anorexia, nausea, vomiting, and kidney disease nearly always appears during the treatment. The renal lesion manifests itself by albuminuria and casts in the urine. It seems as if the albuminuria appears in two different manners. It very frequently coincides with the long febrile reaction and is then usually of short duration, but it may also occur at a later stage of the treatment and may then last longer—weeks or even months. It is particularly this albuminuria occurring late that seems to follow too rapid injections. The longest attack of albuminuria that we observed appeared after three injections at intervals of only four days, and, in general, we have much more frequently seen severe albuminuria when the intervals have been four days than when the interval is increased to six days. Latterly, therefore, as a general rule, we have only given sanocrysin injections once a week, and we have sometimes been able to guard the patient against albuminuria throughout the whole course of treatment. The first two injections only may be given at, say, an interval of two or three days, if no reaction has already appeared. In carrying out the scheme of treatment it is very important to avoid albuminuria as much as possible, because another injection ought not to be given so long as it exists. Moreover, albuminuria is often accompanied by the other intoxication phenomena alluded to, which bring on a state of inanition, with a consequent large decrease in weight. On the other hand, it must be pointed out that the kidney disease is very benign, being chiefly a tubular lesion of a toxic nature, and that in all our cases it disappeared without leaving permanent damage. In a single case, however, there was still a trace of albuminuria after two months.

Although the effect of antitoxic serum in cases of shock has seemed to us very striking, it is more uncertain as yet how much action it has in warding off or arresting the albuminuria, at all events when it is given intramuscularly. The serum injections appear to be particularly ineffective against the late albuminuria, but they probably have an effect upon the kidney disease when it occurs along with the fever reaction at the beginning of the treatment. We have more and more given up the use of antitoxic serum except in shock, and we have tried to avoid albuminuria by increasing the interval between the individual injections in the manner indicated.

The Rationale of Treatment.

When one pays attention to these different factors in the administration of sanocrysin, the treatment is much more simple than it appears on reading the first clinical reports. In the ordinary cases of subfebrile or afebrile phthisis we are satisfied with the dose of 1–2 cg. per kilo suggested by Mollgaard, or more generally 0·5 g. for the first dose, 1 g. for the second dose two to three days later if no reaction occurs, and then 1 g. about once a week. In febrile patients one can begin with a lower dose—for example, half the quantity, and gradually increase it to the full dose of 1 g. In small women 0·75 g. will be sufficient. In cases with high fever it is advisable to begin with a dose of 0·2 g., and increase it very slowly.

Immediately after the injection the patient often feels indisposed and vomits, but this is purely temporary and does not last long. After this, the patient does not notice anything until the reaction caused by the drug occurs. The time which elapses before the reaction appears may vary from a couple of hours to one or even two days, and the first sign of the reaction is a rising temperature.

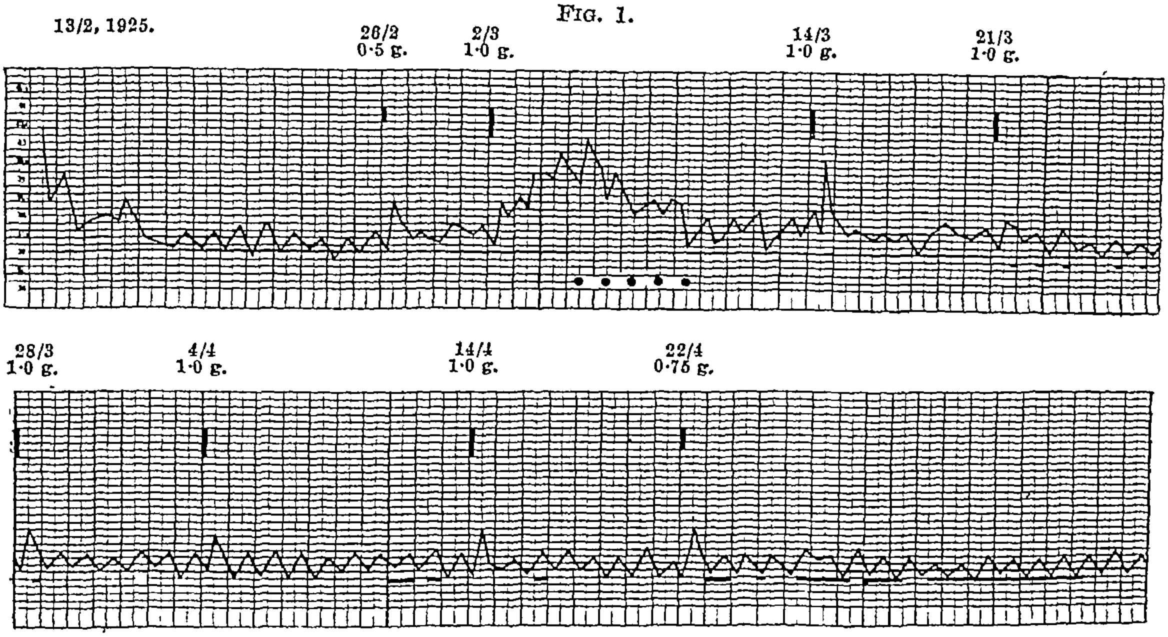
The rise of temperature, in the majority of my patients, has run a fairly typical course. After one or two sanocrysin doses a rise of temperature has occurred in the course of a few days, continuing for one to two weeks, exhibiting a more or less rapid rise and a steady fall to the normal again. This part of the temperature curve often shows a perfectly regular course in its rise and its lytic fall. The subsequent rises were, however, short ones, lasting as a rule only one day, the temperature falling to normal again the day after or in a few days' time, and they get smaller and smaller for each injection, and finally cease.

A rash usually appears during the first long temperature rise. It first takes the form of a morbilliform exanthema which, however, soon becomes general and confluent, so that in the course of a day or two it looks like a scarlatinal rash. The eruption persists for a few days to a week and then disappears without leaving any trace. There is commonly no exanthema or at any rate only a slight and evanescent one after the subsequent short reaction. During the long fever reaction there is frequently general malaise with nausea and anorexia, and sometimes vomiting. In other cases the general condition is very little affected. More or less pronounced pain and tenderness of the joints often occurs during the first fever reaction, passing from joint to joint just as in rheumatic fever.

The accompanying curve illustrates such a typical fever reaction in a case where no serum was given (Fig. 1).

In other cases, however, the fever reaction is less typical, and takes the form of a rapid rise in temperature which in the course of a few days drops to normal, and the long fever reaction referred to is not seen. In many cases the fever reaction is, on the whole, very slight and may even be entirely absent. This is seen especially in old cases of chronic fibroid phthisis. In fresh cases the reaction, on the contrary, may be much more severe, and in a few cases we have seen the long fever reaction recur once or twice, sometimes associated with swelling and tenderness of the lymphatic glands of the neck. In some cases, as mentioned, albuminuria and casts in the urine occur even during the long fever reaction, in others albuminuria does not appear until after the subsequent sanocrysin injections. While albuminuria is present the nausea and anorexia are more marked.

FIG. 1.



The thick horizontal line indicates albuminuria; the thick perpendicular line, injections of sanocrysin; and the black dots, exanthema.

From our experience up to the present, therefore, the treatment with sanocrysin resolves itself into a short series of injections whose effect on the patient's temperature normally diminishes with each injection. At latest after the seventh to eighth injection the patient, as a rule, does not react at all to the injections or at any rate does so only with a slight rise in temperature. The treatment is then at an end for the time being, but can be repeated after a longer or shorter pause. When we have repeated the injections of sanocrysin after an interval of one or more months we did not observe typical temperature rises as in the first treatment, but, at most, a small rise lasting one or two days or else no reaction at all.

As has been said, the patients are subject to unpleasant subsidiary effects in various ways during the treatment. Even in the absence of these the patient's general condition is often rather badly affected, as shown by the more or less marked loss in weight, which may be very considerable and reach 5–10 kg. or more. When the treatment is over the patient usually quickly recovers and there is a rapid increase in weight. In a few cases we saw very troublesome and extensive desquamating dermatitis during the treatment which, however, disappeared in all cases with suitable local applications. It appears to be quite distinct from the typical initial exanthemata. The cases are much like the dermatitis sometimes seen after treatment with salvarsan.

With the cautious treatment described we have only observed very mild local phenomena. The expectoration became rather more profuse at first, and sometimes more râles were heard in the affected parts; these local reactions may be entirely wanting. We have not witnessed any real lighting up of the tuberculous lesion in the lungs during the treatment. In two cases, however, an exudative pleurisy occurred. On another occasion otitis media developed, but a chance occurrence cannot in this case be absolutely excluded.

Results of the Treatment.

Passing now to the question of what effect we observed in the patients we treated, it must, first of all, be stated that the experiences recorded here refer exclusively to cases of ordinary chronic lung tuberculosis—the true lung phthisis. It seems to be here that sanocrysin has its useful field, while the disease, if localised in other parts, especially the so-called surgical tuberculosis, does not appear to be affected in the same way. In a certain number of the patients the favourable effect was very striking, in others it was more doubtful, and in some it could not be detected. We will, for the present, deal specially with the first group and indicate what morbid phenomena we found to be improved after a few months' treatment. We may first cite changes in the general condition, especially cessation of the febrile or subfebrile state and accompanying weakness and asthenia, from which practically all the patients suffered a little on admission. It is, however, obvious that a subjective element enters into the estimate of the condition to a marked degree here.

Of more importance are the objective changes as revealed by the stethoscope, particularly the disappearance of râles or an alteration in their character from the moist râles which are characteristic of fresh progressive processes to the scanty, dry, and sibilant sounds which often persist long after the processes have become quiescent. Finally we have observed as an important sign of improvement that the expectoration, which originally contained bacilli, continues to be free from them, or that all the expectoration has disappeared. On admission, the majority of our patients had an excessively large number of the bacilli in the sputum. After a few injections the numbers decreased very greatly in almost every case, and this was followed by a period when no bacilli could be found by ordinary examination while a few could be detected by the antiformin method. Lastly, the bacilli were constantly absent in a series of examinations, and in most cases did not appear again in the months following the treatment.

Of special importance in estimating the activity of sanocrysin, however, are the changes that can be followed in skiagrams, and I should think that this is a field where a thorough study would prove very profitable for the elucidation of the rationale of sanocrysin treatment and the indications for it. In his experiments on calves Möllgaard saw the acute, chiefly pneumonic, exudative changes in the lungs disappear under sanocrysin treatment, while the miliary tubercles underwent regressive changes much more slowly. Something very similar can be observed in the clinic when one attempts to bring to light by an X ray examination the anatomical changes which take place in the lungs during the treatment. Thus the extensive and rapid changes that can be seen to take place in fresh, largely exudative (pneumonic) processes are striking. Extensive and confluent shadows in the skiagrams can be seen to clear up and disappear while the stethoscopic signs diminish and die out. But also in the mainly productive forms we have seen very pronounced changes. It must be remembered that ordinary chronic phthisis exhibits anatomically a varied picture of exudative-alveolar, more cellular-productive, and purely fibrous lesions. More or less clearing up of the shadows is a frequent and striking phenomenon in all the forms when the skiagrams are compared as the treatment gradually progresses, but at the same time signs of fibrous and cirrhotic processes become more and more evident. The striped and meshed patterns become more pronounced, while the more diffuse soft shadows decrease or disappear.

Summarising the changes seen in the X ray pictures it may be said that they are the same as occur in chronic phthisis which, with appropriate treatment, becomes quiescent and is continuously transformed into typical fibroid phthisis. All the signs of fibroid processes which we are familiar with in skiagrams of phthisical lungs become more and more marked. The fibroid stripes and interlacings quite dominate the picture. But with sanocrysin treatment all this development takes place rapidly in a few months in favourable cases, while with our previous treatment it took years to obtain a similar result.

After the experiences described one would assume that the sanocrysin treatment would be specially effective in recent, not too extensive processes, particularly of an exudative, pneumonic character. This is undoubtedly correct. It is in cases similar to these (as will be seen) that in several instances we apparently obtained at least a temporary cure when the cases were not too acute with high fever. The same does not apply, as might be expected, to the very extensive processes found in phthisical patients who for some years have had a steadily progressing lesion in the lungs, nor to the absolutely chronic cases which must be classified as mainly fibroid phthisis.

We have had little experience of the progressive, continuously febrile cases of phthisis because we regard them as temporarily less suitable for treatment with sanocrysin, but in the severe cases which only have a very slight temperature rise we have in some cases seen remarkably good results even with very extensive lesions, while other cases were not much influenced, so that the processes could not be arrested.

When good results are seen in these one to two-year-old cases of extensive lung tuberculosis they are of the same nature as in the recent cases. The stethoscopic signs diminish, marked clearing-up of the X ray picture is observed, and the general condition is improved, although the sputum still contains bacilli. Usually, however, the number of bacilli in the sputum speedily decreases very considerably and they frequently disappear for a long period, but after one or two months they have appeared again, although in diminished numbers. In cases of cavernous phthisis it is not surprising that it is difficult to rid the sputum of bacilli.

In the old cases of fibroid phthisis of several years' standing one sometimes sees very striking improvement, and in these we have frequently seen the bacilli entirely disappear from the sputum during the treatment. At the same time, the general condition is very markedly improved, although the stethoscopic and X ray changes in these patients are less pronounced. In one of these old cases of fibroid phthisis we have seen the bacilli appear again in the sputum after some months complete freedom from symptoms. Other cases, in spite of freedom from bacilli, continued to have a cough and bring up sputum.

The cavities demonstrated by stethoscopy and X ray pictures deserve special mention. In some cases we saw very characteristic ring-shadows form during the treatment. As is recognised, it is difficult to decide whether this is due to the cavities showing up more distinctly on account of the clearing up of the surrounding tissue, which is seen to occur simultaneously, or whether it is a question of development of a local pneumothorax. At any rate, in one case the latter was definitely present. In other cases we observed a diminution and contraction of the cavity.

Summary of Results.

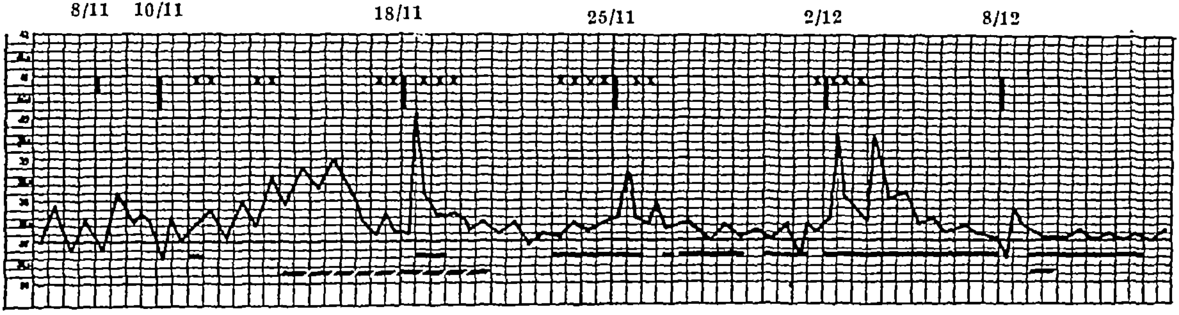
Our material of tested cases is too small and too heterogeneous to give statistics of the results obtained, and we are still far from arriving at a final result. The best impression of the value of the specific is obtained by carefully watching the individual patients during the treatment.

We will, however, give an account of the results of the treatment obtained in 42 patients where the disease was so far advanced that an estimate of its effect could be formed. Eight of these must be regarded as cured in that all subjective signs of the disease have vanished; the sputum, if still present, is always free from bacilli, the râles have entirely or almost entirely disappeared, and X ray examinations show considerable changes in the way described. Most of these patients have left the hospital for several months and feel absolutely well. Another group of 17 patients has shown signs of very considerable improvement subjectively and objectively. Some of them are free from bacilli (eight), four others show only very few bacilli with the anti-formin method. Stethoscopic examination, especially, shows a marked decrease in the extent and number of râles.

A third group comprises nine where the treatment cannot be said to have done any positive good, for after nearly six months' treatment the patients have still signs of active phthisis, which with some of them is practically unchanged and with the rest only shows signs of moderate improvement. Lastly, in six cases the disease has not been arrested by the treatment but has rather tended to spread as time went on. Two of the patients have got a pleurisy, another a tuberculous otitis media. We shall add that during the last five months we have had no deaths among the treated cases of phthisis.

As already emphasised, data such as these have, however, a limited value only. The chief point to us is whether it can be proved that the drug has a true specific action in certain cases in such a way that results can be arrived at, which it has not hitherto been possible to obtain by any other method of treatment. In many cases improvement or a relative cure can, of course, be obtained also by sanatorium treatment or by inducing pneumothorax, but with the sanocrysin treatment we have observed take place in a number of cases such rapid and distinctly favourable changes as could not, in our opinion, have been attained in any other way.

FIG. 2.

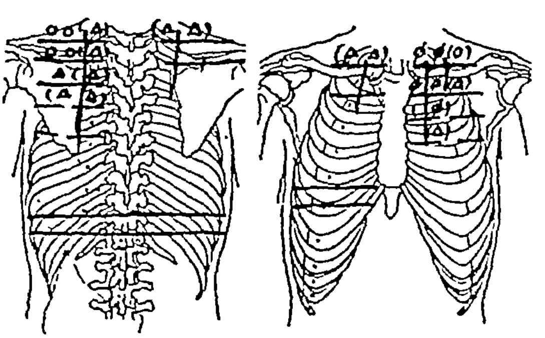


The thick horizontal line indicates albuminuria; the thick perpendicular line, injections of sanocrysin, 0·5 g. given on Nov. 8th and 1·0 g. on the subsequent occasions; the crosses, injections of 20 g. antitoxic serum; and the interrupted line, rash.

According to our experience the cases best suitable for treatment with sanocrysin are cases of phthisis where the infection of tuberculosis has appeared in the course of the last year. In reality we have in 65 per cent. of such cases been able to observe good results, and all the really cured cases belong to this group. Much more uncertain are the results in the very frequent cases of older and extensive disease, and especially when they are in a feverish and progressive phase of the disease.

Of course, one must be prepared to find that there are many cases where no benefit can be derived from the treatment, and also that the treatment will prove injurious in some cases when used without caution. In patients who have had marked signs of phthisis for some years it will often be questionable whether the disadvantages and length of the treatment do not outweigh the benefit which can be expected to ensue. As, however, we have seen quite astonishing improvement in some cases of this type the indications for sanocrysin treatment cannot as yet be laid down with any degree of certainty.

FIG. 3.



Radiological examination, Nov. 11th, 1924.

A Successful Case Narrated.

We add the history of a clinical case. Our intention is only to show that sanocrysin can really exercise a specific action. Not until later on can the final results and the indications for the treatment be determined. It is probable also that the method may be further developed so as to extend its sphere of usefulness and to avoid the inconveniences and dangers which are still attached to it.

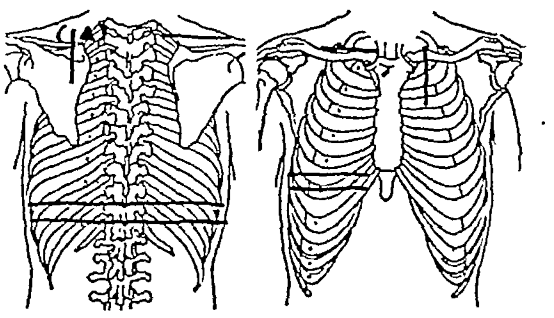
Line, K. Cl., 26 years old. Married to a farmer. Admitted on Nov. 4th, 1924; discharged on Dec. 21st, 1924. A sister died of tuberculosis of the lungs when the patient was 5 years old. Another sister had tuberculosis of the lungs 30 years ago but is now well. The patient was healthy until nine months ago, when she got cough, weakness, night sweats, and fever. Tubercle bacilli were demonstrated in the sputum. There was hoarseness now and again.

Condition on admission.—General condition good. Temperature on Nov. 5th, 37·0°–37° C.; on the 6th, 37·6°–37°; on the 7th, 37·0°–36·8°. Appetite good; slight cough; *sputum scanty; T.B. present. Urine*: no albumin; *hæmoglobin*, 82 per cent. Height, 150 cm. Weight, 50·5 kg. Stethoscopic examination on Nov. 4th:—Left lung: In almost all the upper half there were signs of active disease: dullness, bronchial breathing, and numerous fine and medium fine, mostly moist, râles. Right lung: In the supraclavicular and supraspinous regions there was a slight dullness, bronchial breathing, and fine, moist râles on coughing.

Treatment with sanocrysin. No serum injection until after the second dose. Six injections consisting of a total of *5·5 g.* Nov. 8th, 0·5 *g.*; 10th, 1 *g.*; 18th, 1 *g.*; 25th, 1 g.; Dec. 2nd, 1 g.; 8th, 1 g. The temperature is recorded in curve (Fig. 2).

Stethoscopic examination after termination of the treatment on *Dec. 21st, 1924. Left lung: Dullness unchanged* over almost all the upper half, but only bronchial breathing in the supraspinous region and in the front of the chest to the second rib. The râles had disappeared very considerably in numbers and in extent, and were now heard only in the supraspinous region and as far as the second rib in front. No moist râles, but only dry and partly dry ones were now heard only on coughing. Right lung: Slight dullness over apex as on admission, bronchial breathing over apex in front without râles, and bronchial breathing behind in supraspinous region accompanied by a few partly dry, medium-fine râles with the first cough.

FIG. 4.



Radiological examination, Jan. 16th, 1925.

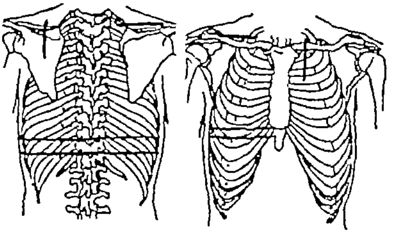
Weight: On Nov. 4th, 50·5 kg.; on 11th, 51·7 kg.; on 22nd, 50·5 kg.; on Dec. 7th, 48 kg.; on 10th, 47·7 kg. The urine contained up to 3 per cent. albumin periodically. Last trace on Dec. 13th (Fig. 2).

Only a few bits of sputum. Latterly only a single mucopurulent pellet every three or four days. On Nov. 8th, T.B.+; on 25th, T.B.+; on Dec. 9th, T.B.−; on 17th, T.B.—. Pirquet reaction: On Nov. 21st, +; and on Dec. 18th, +. General condition on discharge excellent. No more weakness. Temperature normal.

Twenty-five days later was again in hospital from Jan. 15th to 25th, 1925. General condition continued to be good. Temperature normal. No albuminuria. No cough or expectoration. On stethoscopic examination on Jan. 16th only a few dry râles were heard on coughing in the left supraspinous region, otherwise there were no râles. There was no longer bronchial breathing at left apex. Bronchial breathing at right apex over clavicle and spine of scapula. On Jan. 24th practically no râles could be heard.

The skiagrams (represented schematically in Figs. 3, 4, and 5) showed a shadow composed of patches partly arranged in groups in the upper two-thirds of the left lung, and some retraction of the apex of the lung. On the right side there was diffuse darkening of the apex. After the cure the skiagram showed that both apices had cleared up, and, on the whole, only indefinite and rather doubtful changes were present.

FIG. 5.



Radiological examination, Jan. 24th, 1925.

The patient came in with subfebrile phthisis which had produced symptoms for nine months. A stethoscopic examination showed signs of fresh tuberculosis in the upper half of the left lung with numerous fine, moist râles. In the right apex there were a few fine, moist râles. During the treatment the râles disappeared gradually and on discharge, seven weeks later, there were only some scanty, dry, and medium dry râles in the left apex and a few in the right. Twenty-five days after discharge only a few râles were heard in the *left apex* and a week later none at all. The bronchial breathing in the left apex had also disappeared, but there was still bronchial breathing over the right clavicle and spine of the scapula. General condition was excellent. The weight increased, and a month after the treatment was started bacilli could no longer be found in the *sputum*. The X ray examination showed a clearing up of the shadows at the apices in conformity with the stethoscopic investigation. The patient must be regarded provisionally as cured by the treatment.

Conclusions.

From our present knowledge I think we can formulate the *following preliminary* conclusions about the sanocrysin treatment: (1) Sanocrysin has a specific curative action on tuberculosis of the lungs. (2) It does *not seem* to have the same effect on extrathoracic localised tuberculosis (surgical tuberculosis, meningitis, &c.). (3) It is very effective on fresh tuberculosis of the lungs that has been manifest less than one year. (4) In older cases the effect of the treatment is uncertain. (5) It is *difficult to use it* in febrile cases, but some good results may be obtained in old cases of apyretic fibrous phthisis. So far it has not been able to cure acute lobar tuberculous pneumonia. (6) In ordinary cases a treatment lasts three to four months. (7) Generally the dangers may be *avoided when the treatment* is carried *out in the* right manner and with caution. (8) The antitoxic serum has a curative effect on acute shock. Its effect in preventing albuminuria is not clear, and further investigations are necessary.

CHOLECYSTOGRAPHY IN ITS APPLICATION TO THE DIAGNOSIS OF CHOLECYSTIC DISEASE.[*]

BY RUSSELL D. CARMAN, M.D.,

CHIEF OF THE SECTION ON ROENTGENOLOGY, MAYO CLINIC,
ROCHESTER, MINNESOTA, U.S.A.

DURING the last 15 months more than 1100 patients have been examined at the Mayo Clinic by cholecystography. The sodium salt of tetrabromphenolphthalein and that of tetraiodophenolphthalein were used, and each salt was administered orally and intravenously.

Sodium-tetrabromphenolphthalein: Intravenous Administration.

One hundred and seventy-eight patients were given sodium-tetrabromphenolphthalein intravenously. The patients were hospitalised and kept under strict dietetic regimen during the period of examination. The dye was given in a standard dose of 4·5 g., dissolved in 40 c.cm. of triple distilled water, sterilised for 15 minutes in a boiling water-bath and cooled for use. It was administered *in two equal portions one-half* hour apart, and injections were made slowly, from five to seven minutes being consumed. The median basilic vein was used when possible. Rontgenograms were made as a routine at the fifth, eighth, and twenty-fourth hour after giving the dye.

Notwithstanding the precautions mentioned, more than half the patients experienced systemic reactions in varying degree. In most cases the symptoms were trivial, but in 10 per cent. the reaction was marked and in 2 per cent. severe. The typical severe reaction began within five or ten minutes with a sense of uneasiness, followed by pain in the dorsal and lumbar region, flushing of the skin, and a rise of from 10 to 50 mm. in blood pressure, followed within three to five minutes by a sharp fall. With the fall of blood pressure, patients sometimes had intestinal *cramps, nausea*, vomiting, or incontinence of the bowel and bladder. Milder reactions were characterised by flushing of the skin, slight pain in the back, and transient nausea. Occasionally a delayed reaction developed four or five hours after injection.

Normally, with this test, as Graham first pointed out, the gall-bladder will retain sufficient dye to cast a shadow at the fourth or fifth hour after administration. This shadow attains its greatest intensity some time between the eighth and twenty-fourth hours, becomes progressively thinner thereafter, and usually disappears between the twenty-fourth and forty-eighth hours. The shadow is regular in contour and homogeneous. It varies in size and is commonly larger at earlier than at succeeding hours. Abnormal responses include failure of the gall-bladder to fill with the dye, persistent faintness of the shadow, delayed filling, marked delay of emptying, deformity of contour, unvarying size of the shadow, and mottling, or central defects.

Thirty-nine patients of this series were operated on. All proved to have disease of the gall-bladder, and 25 also had stones. In 19 of the 25 cases with gall-stones the gall-bladder failed to fill with the dye; shadows of the gall-stones themselves were visible in *only six cases of the 19*. Dye entered the gall-bladder *in six cases, but in two of these* the shadow was mottled with transparencies; in one the denser shadow of stones was seen within that of the gall-bladder; and in one the gall-bladder was faintly depicted at the eighth hour only. In only two cases of the 25 could the findings be construed as negative. A definite lesion of the gall-bladder without stones was found at operation in 14 cases. In eight of these the gall-bladder failed to fill with the dye. Its shadow was visible at the twenty-fourth hour only in one case, and at the fifth and eighth hours only in two others. No abnormalities were observed in the remaining three cases.

---

[*] Abstract of a paper read at the Section of Radiology, Subsection Diagnostic Radiology, International Congress of Radiology, London, July 1st, 1925.

Sodium-tetrabromphenolphthalein: Oral Administration.

The bromine salt has been given orally to more than 800 patients. No preparation of the patient is required. The dose is proportioned to the body-weight and ranges from 4 to 7 g. It is given in ordinary gelatin capsules containing a gramme or a half gramme each. The patient is instructed to take the capsules at intervals during the evening meal, drinking water freely, and present himself without breakfast for the examination next morning at 8 o'clock. Rontgenograms are made at the twelfth, fifteenth, and twentieth hours after the dye is taken.

Reactions following oral administration of the bromine compound have been relatively few and never grave. Occasionally complaint has been made of nausea, a few patients have vomited, and in rare instances catharsis has occurred. Shadows of the gall-bladder obtained by the oral method are commonly less dense than those observed after intravenous administration. In about half the normal cases the shadow disappeared by the twentieth hour. Otherwise the principles of interpretation and the distinctions between normal and abnormal responses to the test are the same for both methods.

One hundred and forty patients of this series have been operated on. At operation 71 patients were found to have gall-stones. In 36 cases of this group no shadow of the gall-bladder had been seen; shadows of the stones were evident in seven of the 36. A faint shadow of the gall-bladder was noted in 15 cases. Mottling of the shadow by stones was observed in 15 cases. In five cases the response to the test was normal. Marked disease of the gall-bladder, without stones, was discovered at operation in 33 cases. In 16 of these the gall-bladder had failed to cast a visible shadow with the dye, and only a faint shadow was seen in 11. In five cases the rontgenological findings were considered to be normal. The third group comprised 17 cases in which the gall-bladder when removed revealed pathological changes of minor degree. At the rontgenological examination the gall-bladder had failed to cast a shadow in seven and responded normally in ten. In the fourth group of 19 cases the gall-bladder was explored in the course of operation for other lesions and adjudged to be normal. No abnormality had been discovered at the rontgenological examination in 16 of them. In three cases no shadow of the gall-bladder was visible.

Sodium-tetraiodophenolphthalein: Oral Administration.

Sodium-tetraiodophenolphthalein was given orally to a limited series of patients. The standard dose was 0·08 g. for each kilo of body-weight, but not in excess of 6·0 g. to a patient. Both enteric-coated pills and plain gelatin capsules were tried. Almost all the patients who received the pills experienced purgation, vomiting, or nausea. These disturbances occurred less often from the capsules, but more frequently than from the bromine salt. Rontgenograms were made at the same periods and under the same conditions with respect to fasting as in the oral method with the bromine salt, and the same criteria were applied in interpretation.

Up to the present 25 patients have been examined with the iodine salt by mouth. Three have been operated on. All three had given normal responses to the test. In two cases the gall-bladder was accounted to be normal on surgical exploration in the course of operation for other lesions. In the third case the gall-bladder was removed, but only minor pathological changes were found.

Sodium-tetraiodophenolphthalein: Intravenous Administration.

Patients to whom the iodine salt was given intravenously were not hospitalised, but were subjected to the same dietetic regimen as those who received the bromine salt intravenously, and rontgenograms were made at the same periods. A dose of from 3 to 3·5 g. was given, dissolved in 28 c.cm. of triple distilled water, and administered at one sitting. Preparation of the solution was identical with that of the bromine salt. No reactions occurred, and this was ascribed in part to exceptional purity of the drug. The shadows obtained were somewhat denser than those obtained with the bromine salt.

This series comprised 32 patients, of whom 11 have been operated on. Three of these patients had gall-stones; in two cases there had been no shadow of dye in the gall-bladder, and in the other the shadow was mottled. Five patients had marked *cholecystitis* without stones; in three the gall-bladder had not been depicted with the dye, while in two the shadows were normal. Slight disease of the gall-bladder was discovered in three cases; in two the rontgenological examination had been negative, and in the third case the shadow was faint.

Rationale and Weight of Signs.

Among the cholecystographic phenomena indicative of disease, failure of the gall-bladder to fill with the dye in sufficient quantity to cast a shadow seems to rank first in frequency and to be unexcelled in diagnostic value. Scarcely less reliable is constant faintness of the shadow. Potential causes of complete absence or persistent faintness of the shadow are of two types—namely, those which interfere with entrance of the dye-laden bile into the gall-bladder, and those which interfere with concentration of the bile. A stone obstructing the cystic duct or a large volume of stones, sand, or abnormally thickened bile in the gall-bladder should mechanically exclude or impede entrance of bile carrying the dye. Empirically, at least, this association has been found repeatedly. Swelling of the mucosa of the duct, spasm, or constricting adhesions would logically also have this effect.

Cirrhosis or other grave disease of the liver might hamper excretion of dye in the bile and thus lead to an error of interpretation, but I have encountered no such instance. It is difficult to appraise the effect of hepatitis alone because many other factors are involved and it is a common accompaniment of cholecystic disease. Rosenthal's experiments tend to show that the liver has a large "factor of safety" and that extensive damage is required to impair hepatic function. At all events, in some cases of this series, in which hepatitis and cholecystic disease were associated, the gall-bladder was normally visualised.

An increase of intensity followed by a diminution is the usual normal finding. This definite order is hardly to be expected always, as it may possibly be modified by the drug used, the method of administration, variation in the period of rontgenography, or failure of the patient to comply with directions as to taking food. Mottling of the shadow demands some caution in interpretation. When produced by stones which are denser than the dye there is little chance of error. Mottling due to transparent cholesterin stones is sometimes fairly characteristic in appearance. In many instances, however, the shadow-defects are not markedly different from those caused by gas in an overlying segment of bowel, and this source of error must be guarded against. Papillomas, if of sufficient size, should also produce mottling.

Unvarying size of the shadow at all periods may be construed as evidence that the gall-bladder lacks normal elasticity. If, however, the intensity of the shadow varies and is fairly pronounced at any time, unchanging size loses force as an index of disease, and one would hardly venture to base a diagnosis on this sign alone.

By all the methods described the normal gall-bladder seldom fails to cast a shadow on the first films made. After intravenous administration of the dye a shadow usually remains at the twenty-fourth hour. After oral administration the gall-bladder may or may not be empty of dye by the twentieth hour. Differences between the food regimen of the two methods probably account for the disagreement. Moderate delay of filling or emptying, or acceleration of either may have a significance which will be learned with experience. At present one is obliged to construe such minor abnormalities with reserve.

Local deformities of contour were rarely observed in this series. In one case a slight flattening of the fundus seemed unrelated to the pathological changes found at operation. In another the fundus was very pointed, but the gall-bladder was deemed to be normal on surgical exploration. Adhesions about the gall-bladder were present in several cases, but no deforming effects on the shadow were noted, although such a possibility is obvious.

Apparently least significant of all factors is the position of the gall-bladder. In persons of the slender habitus it is usually situated low and mesially, while in those of the broad habitus it is likely to be placed high and laterally.

Errors of Diagnosis.

The affirmative diagnoses of disease appear to be well sustained, and there were few disappointments in the series. Negative findings with the dye tend to be somewhat less reliable. Occasionally a definitely diseased gall-bladder will respond normally to the test. Even the shadow of a gall-bladder containing stones may sometimes have normal characteristics in general. The most serious obstacle to the accuracy of a negative diagnosis is the gall-bladder in which are only minute pathological changes, probably a residue from more pronounced disease in the past. Such a gall-bladder more often responds normally to cholecystography and may be apparently normal on surgical exploration. If the history warrants its removal, it will seldom fail to reveal at least microscopic evidence of disease.

Comparison of Methods.

Intravenous administration of the dye offers advantage in superior control of the patient, certainty that the specified dose of the drug has been given, and emphasis of the shadows obtained. Its disadvantages are the requirement of a punctilious technic and the hazard of local or systemic reactions. With identical technics the bromine salt given intravenously seems to be more provocative of systemic reactions than the iodine salt, if the latter is pure.

Simplicity and freedom from grave reactions are the principal advantages of oral administration. With either salt, nausea and purgation ensue occasionally. The iodine combination, even when pure, seems to produce these discomforts more often than the bromine. Vomiting after taking either drug, unless early, has apparently had no material effect on the shadow. Dye in the intestinal contents produces shadows which may be a little confusing and might possibly conceal the shadow of the gall-bladder, but such circumstances are infrequent. Lack of certainty that all of the drug has been taken as directed is another minor objection. The question may also arise as to whether defective absorption from the intestine may not be a cause of abnormal findings. However, all these objections and doubts seem to have little basis, for in this series the diagnostic results from all methods have been about equal.

From these considerations it will be apparent that my present preference is for the oral use of the bromine salt as a routine, and the iodine intravenously to check doubtful cases.

ANURIC DIABETIC COMA.

BY A. CLARKE BEGG, O.B.E., M.D., CH.B. EDIN., M.B. LOND.,

HONORARY PHYSICIAN, SWANSEA HOSPITAL.

THE exact cause of diabetic coma is still doubtful, but it is regarded as the end-result of acidosis and due, directly or indirectly, to the accumulation of acetone bodies in the blood. All the authorities take this view though they recognise various clinical varieties. For instance, Tidy[1] gives three types: (1) Dyspnœic; (2) alcoholic; (3) a type with collapse. Osler[2] gives a somewhat similar classification. Even Joslin[3] in his classical book regards acidosis as the essential factor in diabetic coma, although he speculates about two cases with anuria which obviously fall into the renal or anuric type which I am about to describe. Graham[4] goes a step further and describes two main types—viz., with well-marked hyperpnœa and without obvious hyperpnœa—but does not show the essential differences between the two types. MacLean[5] admits that it is possible to have diabetic coma in which the tests for acidosis give practically normal results, but he draws no distinction between the nature and course of the disease in these cases and in the ordinary acidosis cases.

Clinical Types of Coma.

Until the advent of insulin it did not much matter how one classified cases of diabetic coma—practically all were fatal. With the aid of insulin, however, the cases of ordinary, frank diabetic coma usually responded to treatment in a marvellous way, but very soon one was discouraged to find that certain patients died in spite of the new treatment. I noticed that the patients who died were those who had little or no acidosis, and as far back as December, 1923,[6] I recognised two distinct types: (1) ordinary type associated with acidosis, which, as a rule, recovered with insulin treatment; and (2) type with little or no acidosis ("post-operative type"), all of whom died in spite of the most energetic treatment. I recorded three cases at that time and since then I have had five others, four of whom died. Thus out of eight cases of this type seven have died. With the help of Dr. Milligan and Dr. Lindsay, my house physicians, to whom I am greatly indebted, the cases were observed very closely and we found that with insulin treatment any slight acidosis present was easily abolished, the urine was rendered sugar-free, and the blood-sugar was brought down to normal limits. Instead of corresponding clinical improvement, however, the patients became worse, and they secreted less and less urine until there was *complete anuria* before death.

In all these cases there was some albumin in the urine and usually a few casts. The concentration of urea in the urine was usually low and in the blood invariably high; in one case it reached 206 mg. per 100 c.cm. There was seldom noticeable thickening of arteries or high blood pressure. Most cases were of some standing, but one, a young man, gave a history of only two to three weeks' illness. The blood-sugar was always very high. Clinically, the most prominent symptoms were vomiting, restlessness, and feeble, quick pulse. The type of respiration varied, sometimes Cheyne-Stokes, never typical air-hunger. Little or no smell of acetone in the breath, but the tension of the eyeballs was lowered as in coma of the ordinary type. Sometimes there was quiet delirium, but never twitching of muscles or epileptiform convulsions. Usually some amount of consciousness was retained till very shortly before death.

Cause of Anuric Type of Coma.

What is the cause of the coma in such cases? It cannot be acidosis, neither can it be the mere excess of blood-sugar, for as great an excess may be present without coma; and, moreover, the blood-sugar may be reduced to normal with insulin and yet no improvement result. It is possible that the essential cause is the production of some unrecognised toxin resulting from the faulty metabolism in diabetes. Whatever the primary cause, it soon became clear that the immediate cause was some kind of defective action of the kidneys. Two constant features were very high blood-urea and diminished secretion of urine, ending in complete anuria. The natural suggestion then was that the coma was due to uræmia, but against this were the facts that beyond slight albuminuria many cases showed no evidence of inefficient kidneys up till the onset of coma, while the symptoms were different from those commonly found in uræmia. They resembled much more the symptoms of so-called urinæmia, found in obstructive suppression of urine, in which the severe and acute mental disturbances, the sudden amaurosis, and the epileptiform phenomena in general of uræmia are lacking.

We had opportunities of doing post-mortem examinations in several cases, and my thanks are due to Dr. A. F. S. Sladden and Dr. Milligan for their help in this connexion. Certain changes were found which suggest that the kidney is an all-important factor. Dr. Milligan is at present engaged in a research on this question which I am sure will be of great value.

Prognosis and Treatment.

Meanwhile, it is very desirable that these cases should be recognised clinically. First for prognosis. If a patient in diabetic coma shows abundant glycosuria with high blood-sugar and high blood-urea, absent or slight ketonuria, but with a trace of albumin in the urine, the prognosis is very grave. Up till a short time ago I would have said that it was hopeless, as my first seven cases all died, and this in spite of all kinds of treatment for the suppression of urine in addition to the ordinary treatment of diabetic coma. Recently, however, I have had one case which recovered. The only difference in the treatment of this case was that two pints of normal saline were given subcutaneously *at the outset*, and four pints more were introduced during the first 24 hours. Whether this was the determining factor in recovery is, of course, doubtful, but as it is the only case which has recovered, I would advise this treatment being carried out at once in any similar case. Of course, all the other cases had saline administered, but the rectal route was usually tried first before resorting to the subcutaneous or intravenous method, and possibly valuable time was thus lost. It is important, therefore, both for prognosis and treatment, that this variety of coma should be recognised as soon as possible and the most energetic treatment given without delay. This warning is the more necessary, as cases of this kind often appear to be of less severity than the ordinary cases associated with marked acidosis.

Summary.

To summarise, the points common to both varieties of coma are: (1) Drowsiness going on to coma; (2) vomiting (usually) and constipation; (3) lowered tension of eyeballs; (4) raised blood-sugar; (5) glycosuria; (6) tendency to heart failure.

The differences between the two types are:—

Ordinary Diabetic Coma with Acidosis.—(1) Blood: Blood-sugar moderately high: blood-urea about normal. (2) Urine: Good quantity and soon increases with treatment; much acetone and diacetic acid; no albumin (usually). (3) Clinical: Coma usually deep some time before death; air-hunger marked; odour of new-mown hay in breath. (4) Prognosis: Insulin treatment usually cures.

Diabetic Coma with Absent or Slight Acidosis.—(1) Blood: Blood-sugar very high; blood-urea very high. (2) Urine: Usually small quantity going on to complete anuria; little or no acetone or diacetic acid; some albumin. (3) Clinical: Coma often not deep till just before death; air-hunger absent or slight; no odour of new-mown hay in breath. (4) Prognosis: Usually fatal from anuria.

Whether this type of diabetic coma without acidosis is a distinct entity is doubtful, as some of the cases began with the typical signs of ordinary diabetic coma, and it was only when the acidosis had cleared up under treatment, without corresponding clinical improvement, that they showed themselves to be of the definite anuric type described above. Be that as it may, it is certain that as regards symptoms, physical signs, course and prognosis, it is a distinct clinical type and that the immediate cause of death is suppression of urine.

The condition might be called diabetic coma of the renal type, but until further knowledge is gained the most suitable name would appear to be "anuric diabetic coma." This has the advantage of emphasising the outstanding symptoms of the disease and the one for the relief of which all our energies have to be directed.

THE TECHNIQUE OF SPLENIC PUNCTURE IN THE DIAGNOSIS OF KALA-AZAR.

BY PHILIP MANSON-BAHR, D.S.O., M.D. CAMB.: F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES.

SPLENIC puncture, as a means of clinching the diagnosis, is essential in kala-azar. By some this procedure is regarded with a certain measure of apprehension on account of the risk of lacerating the splenic capsule and thereby causing intraperitoneal hæmorrhage. I am convinced that, if the patient is partially anæsthetised and the exploration needle is sufficiently sharp and of correct calibre, little or no danger is to be apprehended. The patient should receive 1/100 gr. atropine about half an hour before the puncture is to be performed, and the skin over the costal margin should be infiltrated with 1 per cent. novocaine solution. The entry of the needle through the abdominal wall and the piercing of the peritoneum will thereby be rendered to a great extent painless, with the result that the patient will not flinch or suddenly retract the diaphragm, a movement which is liable to lacerate the splenic capsule. The needle employed should be of a bore sufficient to admit of a plug of splenic tissue, but should not be so stout as actually to lacerate the pulp. (Allen and Hanburys' No. 10 size I find to be the most suitable; this needle is also of the correct length—40 mm.)

Considerable difficulty may be experienced in obtaining microscopic preparations free from aspirated blood comprising mostly pulp cells containing the Leishman-Donovan body. For this purpose the plunger of the aspirating syringe should not be driven home to the extremity of the barrel, but an air space of 1 cm. at least should intervene. Traction on the piston must be steadily kept up directly the needle is ascertained to have entered the organ, and aspiration must cease directly blood can be seen entering the barrel of the syringe.

On retraction of the syringe the aspirated tissue and blood is blown out on to a clean microscopic slide and examined in a darkened room by means of an electric pocket torch (the "Ever Ready" being the most suitable for the purpose). The light being held underneath the drop, the portions of spleen pulp can be easily demonstrated like small grains of sago floating in the blood-stained fluid. These particles of tissue are then picked out by means of a fine platinum loop and spread upon clean slides. Preparations of splenic pulp cells are thereby obtained, in which the parasites can be demonstrated without difficulty by means of Leishman's stain.

In a splenic puncture recently undertaken the success of this measure was remarkable. The resulting films consisted of a mass of splenic endothelial cells, few red blood corpuscles being visible in the preparation.

Reviews and Notices of Books.

PATHOLOGY AND BACTERIOLOGY OF THE EYE.

Second edition. By E. TREACHER COLLINS, F.R.C.S., Consulting Surgeon to the Royal London Ophthalmic Hospital; and M. STEPHEN MAYOU, F.R.C.S., Surgeon to the Central London Ophthalmic Hospital. London: W. Heinemann. 1925. With 4 coloured plates and 300 figures. Pp. 731. 42*s*.

THE authors of this work have long been recognised as authorities on ocular pathology, and the present edition embodies chiefly the results of their own researches, excellently illustrated by figures, many of them reproduced from original papers in the Transactions of the Ophthalmological Society.

The first chapter on aberrations in development is divided into five sections in which the various abnormalities that are met with are traced to their respective periods of origin in embryological history. Incidentally, we find some interesting explanations of some not uncommon clinical appearances—e.g., the so-called shot-silk or watered-silk retina, pseudo-optic neuritis, and the congenital crescent that is sometimes found and which has nothing to do with myopia. On the subject of congenital colour-blindness the authors profess themselves on the side of those who attribute it to some, at present unascertained, aberration in the cones. Chapter II., on neoplasms, includes figures and descriptions of various uncommon forms of cysts. Chapter III., on disturbances in the circulation and constitution of the nutrient fluids of the eye, deals with arterial and venous obstructions, hæmorrhages, and serous effusions. It also explains the mechanism of normal intra-ocular tension, and deals with the problems connected both with glaucoma and with diminished intra-ocular tension or hypotony, to which subject Mr. Collins has given special attention. In Chapter IV., on injuries, special interest attaches to the explanation of the condition known as "commotio retinæ," following a contusion of the eyeball without rupture of its coats. The drawing of a microscopical section shows a subchoroidal hæmorrhage compressing the capillary layer of the choroid. If the blood is absorbed soon circulation in the choroidal vessels is re-established and the retinal functions are regained; if, on the other hand, it is long in being absorbed, the rods and cones atrophy, the pigment cells become visible, and sight is permanently impaired. Chapter V., which has been largely rewritten, deals with inflammation—in the first place the changes common to all inflammatory processes, and in the second the modification of the general processes of inflammation in the various structures of the eye. Chapter VI. deals with parasitic diseases affecting the eye, bacteria, fungi, and animal parasites, *Spirochæta pallida* being classed under the third heading. Under a fourth—diseases which are probably but not certainly due to micro-organisms—are included trachoma, vernal catarrh, and sympathetic ophthalmitis. In Chapter VII., dealing with degenerations, various forms of cataract are dealt with, and under the heading of neural epiblastic degenerations is included retinitis pigmentosa, in accordance with the theory held by Mr. Collins that it is actually caused by an abiotrophy of the retinal cells. An appendix on laboratory methods completes the book.

This work does not pretend to be encyclopædic or final. There is, for instance, no reference to those concussion injuries to the eye caused by bullet wounds of the orbit described by Lagrange, and the authors have not attempted to include all the findings of slit-lamp microscopy of the living eye, a study which is as yet in its infancy. Within its self-imposed limitations, however, the work is a thoroughly sound one, and we recommend all ophthalmic specialists to become familiar with it.

CHEMISTRY IN THE SERVICE OF MAN.

Third edition. By ALEXANDER FINDLAY, M.A., D.Sc., F.I.C., Professor of Chemistry, University of Aberdeen. London: Longmans, Green and Co. 1925. Pp. 300. 6*s*.

PROF. FINDLAY belongs to that small group of scientists who are able to write for both the advanced student and the lay reader. The work has been enlarged and three new chapters have been added. The first of these deals with radio-activity. Here the author traces the growth of the present-day theories with regard to the constitution of matter. Dalton, in 1803, taught that the atoms were solid, undividable bodies, but even so early as 1816 Prout was led to suggest that the atoms of different elements were all built up of some primordial substance which he called protyl. Prout put forward this theory on account of the atomic weights of the elements being, in most cases, whole numbers. This theory did not receive much support until Mendeléeff described the periodic law. The next line of approach came through the study of electrical discharges in vacuo, and from these two sources the present ideas of the structure of the atom is evolved. Confirmatory evidence was obtained by studying the properties of radium. The second new chapter is on the rare gases of the atmosphere. Here are described the experiments leading to the isolation and identification of argon, krypton, and allied gases. The third addition deals with metals and their alloys. Here the author considers the methods available for the preparation of these bodies from their ores, and their properties and alloys. Prof. Findlay describes the interesting condition known as "tin plague." He points out that under 18° C. ordinary lustrous tin is unstable and changes into a semi-porous state known as grey tin. If the temperature is very low these changes can take place fairly rapidly, resulting in marked disfigurement of any article made of the metal. A plate is included showing a seventeenth century medal suffering from "tin plague," which completely spoils the otherwise dignified appearance of one Balthasar-Bekker.

In the main, the rest of the work has been left unaltered. Certain sections have been revised and some rewritten. The style and choice of subjects are admirable, and Prof. Findlay is to be congratulated upon the appearance of this third edition of a charming book.

ELEMENTS OF COLLOIDAL CHEMISTRY.

By HERBERT FREUNDLICH, Fellow of the Kaiser Wilhelm Institute of Physical Chemistry. Translated by GEORGE BARGER, F.R.S., Professor of Medical Chemistry in the University of Edinburgh. London: Methuen and Co., Ltd. 1924. Pp. 210. 7*s*. 6*d*.

PROF. FREUNDLICH'S work upon adsorption and other colloidal problems is well known. It is mainly for his work on the mathematical aspect of adsorption that he is famous. Freundlich's adsorption equation has become an accepted scientific fact. It will therefore come as a cheering surprise to the general reader that not a single mathematical deduction is included in this little book. The main body of the work consists of a condensed form of the author's larger book, "*Kapillarchemie*," which has become a standard work on colloids. The volume is divided into two main sections, the first of which sets out the physico-chemical foundations of colloidal chemistry. After an interesting introduction the author deals with capillary chemistry—i.e., the changes occurring at interfaces. This method of attacking the problem of colloids is essentially Teutonic, and this volume is certainly one of the first to be published in the English language in which colloidal chemistry is presented in the form of capillary chemistry. The author considers the events taking place at the interface between liquids and gases, two liquids, a solid and a gas, and finally between a solid and a liquid. By this means the whole of the field is covered, and the first section concludes with two articles on capillary-electrical phenomena, and the problems of interfacial layers. In the second section the author deals with colloidal systems as a whole. Thus the properties of sols, gels, mists, and smokes, and the like are considered.

There are perhaps one or two points which might be criticised. Little or no reference is made to the work of J. Loeb on adsorption in relation to the iso-electric point of proteins. In the second place, it is possible that the author has been too drastic in eliminating all mathematical considerations. A simple mathematical treatment of adsorption would certainly have assisted some students in grappling with larger works.

In the translator's note Prof. Barger says: "I was so impressed by the manuscript of Prof. Freundlich's 'Grundzüge der Kolloidlehre,' that I at once undertook its translation." We have to compliment Prof. Barger, firstly, upon his judgment, and, secondly, upon his ability as a translator.

THE BACTERIOLOGY OF FOOD.

By CUTHBERT DUKES, M.D., M.Sc., D.P.H., Lecturer in Bacteriology, King's College for Women. London: H. K. Lewis and Co., Ltd. 1925. Pp. 180. *7s. 6d.*

DR. Dukes has produced a readable little book which contains much information not hitherto available in a collected form, although it may be found scattered through the pages of larger works. The volume is likely to be appreciated by the students for science degrees, for whom it is primarily written, and it may also be read with profit by both medical and D.P.H. students who are too often content with those aspects of bacteriology which are directly relevant to pathology. About a half of the book is devoted to milk and its products, and perhaps other foodstuffs suffer a little by contrast, but both water and alcoholic beverages receive adequate attention. We consider that the direct search for tubercle bacilli in milk is really a waste of time and energy, and that since Dr. Dukes evidently only teaches on the subject as a concession to ancient usage, he might omit the section. There is a mistake on p. 57 where the virulence test for *B. diphtheriæ* is described as being made by the injection of a "serum slope" into guinea-pigs. The correct practice is to use broth cultures.

AN INTRODUCTION TO SEXUAL PHYSIOLOGY.

By F. H. A. MARSHALL. London: Longmans, Green and Co. 1925. With 72 text figures (some coloured). Pp. 167. *7s. 6d.*

THE conventional text-books of physiology generally contain a most inadequate account of the working of the sexual apparatus, and the average student would probably be pained and surprised if he was asked some very simple questions about it. The truth is that the answers to some of these *simple questions*—why do the breasts hypertrophy during pregnancy, what brings pregnancy to an end, what determines the sex of a child and so forth—have been and in some directions still are quite obscure, and their discussion has been hampered by a mingling of fact and fancy which is unknown in those departments of physiology of less urgent human interest. Since the publication of Dr. Marshall's "Physiology of Reproduction" (with a second edition in 1922) it has been easy to learn what is known on the subject and, which is perhaps more important, to appreciate what is not known and how many ordinary things need investigation. In this country he has made the topic his own, and he now increases our indebtedness to him by publishing a short and simple version which should have a wide circulation. It is intended "for biological medical and agricultural students," is well illustrated (thanks, we suppose, to the existence of the larger book) and cheap, and gives an admirable account of the sexual cycle, pregnancy, lactation, and the influence of the sex-glands, fecundity and the related problems; determination of sex is also discussed. The writing is clear and straightforward. The tangled sentence on p. 131, "the fact that the free-martin and its partner are not derived from the same egg is definitely negatived by there being two corpora lutea," is an exceptional muddle which a new edition will correct, and the difficult task of abbreviating a systematic book seems to have been done very well. We cordially commend the book for itself and as an introduction to the fuller account.

BRONCHIECTASIS.

Traitement Chirurgical de la Dilatation Bronchique. By Dr. P. GUIBAL. Paris: Masson et Cie. 1924. Pp. 173. Fr.10.

THE surgery of the lungs and bronchi has not received in France the attention it has long enjoyed in the U.S.A. and Germany. It is to make good this defect that Dr. Guibal has written this little book which deals with such operations as artificial pneumothorax, thoracoplasty, pneumotomy, ligature of the branches of the pulmonary artery, lobectomy, and partial pneumectomy, as far as they concern bronchiectasis. It is disappointing, but not surprising, to find how ineffective many of these procedures are for this disease. An artificial pneumothorax may rid the patient of all his sputum as long as the injections of gas are continued, but soon after the lung is allowed to re-expand the bronchiectatic state returns. Extra-pleural thoracoplasty may be a good palliative remedy in cases of bronchiectasis which are mainly unilateral, but, according to the author, complete recovery can never be achieved in unilateral cases of diffuse bronchiectasis operated on according to Sauerbruch's technique. An interesting account is given of such daring operations as lobectomy, the mortality of which is from 40 to 50 per cent.—a high risk justified only by the desperate prognosis of many cases left in the hands of the physician. This book is a useful introduction to the subject and it does not claim to be more.

THE TEMPORAL BONE.

L'Os Temporal chez l'Homme Adulte: Iconographie et Description de l'Os et de ses Cavités. By PHILIPPE BELLOCQ. Paris: Masson et Cie. 1924. Pp. 128. Fr.18.

THIS monograph, written by Dr Bellocq, on the results of his personal investigations of a large material, is an excellent example of the clearness in description which is so frequently a marked characteristic in French anatomical works. Like most of these, it is written from the surgical or pathological standpoint more than from that of the morphologist, and deals first with the bone as a whole, subsequently treating of the connexions of its constituent parts, the details of each of these parts, and the various cavities contained in the structure. The descriptions are excellent, clear and reliable, and are aided by good figures in line, so that—to the anatomist at any rate—there is no break in the continuity of interest and description. It may be, however, that the purely descriptive standpoint is not the best possible one for the non-anatomical reader when he begins to study the details of the temporal. The bone is the most complex portion of the skeleton, built up by the fusion of parts derived from distinct and separate planes and regions, and it would seem better to give such a reader a mental picture or conception of the bone made up in this way as a preliminary to his detailed study, and a guide to his comprehension of the medley of facts into which he is plunged. This view may be prejudiced, it might perhaps be held to be fallacious.

but it does not, at any rate, keep us from the expression of sincere admiration for this descriptive account of the bone; any clinician who has to do with the temporal bone, and feels that he would like to improve his acquaintance with it, can be advised to procure this book and some sectional bones, when he should have little difficulty in attaining his object.

INTELLECTUAL DEVELOPMENT AND THE ERECT *POSTURE.*

By WM. COLIN MACKENZIE, M.D., F.R.C.S., F.R.S.E., Director of the National Museum of Australian Zoology, &c. Melbourne: Allan Grant. 1924. Pp. 41.

THIS little book has been written in support of Dr. Mackenzie's belief that the assumption of the upright position is the most important factor in the evolution of the human species, that this is inherently a question of muscular development, and that the degenerations and diseases to which the unfortunate human being is prone are mostly to be credited to his failure to keep his muscular system going in the proper way. We have been disappointed with the book. Whether Dr. Mackenzie's creed will stand examination or not could hardly be determined by study of such a small work, but it cannot be said that he has carried out the intentions expressed in his opening pages. The mere account of certain differences in the comparative anatomy of living mammals does not in itself constitute an evolutionary argument. In many respects the little work is an interesting one to read, and in many ways suggestive.

PRACTICAL CHEMISTRY BY MICRO METHODS.

By EGERTON C. GREY, D.Sc., F.I.C., M.R.C.S., Professor of Chemistry, Government Medical School, Cairo. Cambridge: Heffer and Sons. 1925. Pp. 124. *4s. 6d.*

THE author has written a text-book of analysis for medical students in which white tiles are substituted for test-tubes. Reactions are also performed on slides, and the results may be observed by means of a small microscope or by a pocket lens. It is thus possible to conduct a complete course of analysis with great economy. All teachers are aware of the liberality of medical and other elementary students with reagents. A whole set of reagent bottles may be emptied during the analysis of some simple solid. By means of the techniques outlined in this book it would be impossible for the student to waste his reagents. The idea of micro-analysis for elementary students is not a new one, since it has been employed extensively in technical schools and similar institutions in this country for some time. Teachers speak well of the method, and Prof. Grey's book should prove of great value to all engaged in teaching analysis to these students.

TUBERCULOSIS.

Les Processus Naturels de Guérison de la Tuberculose Pulmonaire. By Dr. JAQUEROD. Paris: Masson et Cie. 1924. Pp. 121.

A SOUND knowledge of the physiology and pathology of the lungs invaded by the tubercle bacillus is surely essential to any scientific attempt to cure pulmonary tuberculosis. It would not be necessary to repeat this platitude were it not for the ambitious tendency of human beings to try to run before they have learnt to walk, and to try to cure evils before their causes are known. Dr. Jaquerod's book is a painstaking protest against this tendency as it appears in the field of therapeutics, and throughout the pages of his book his main thesis is that we must penetrate into the secrets of cure by Nature if we expect, in common phrase, to "go one better than" Nature. With a background of 20 years of specialising in pulmonary tuberculosis, he teaches this among other lessons: Give Nature time. Translated into more definite terms, his opinion is that at least a year is required for the clinical recovery of a case of pulmonary tuberculosis. And, as life for the ordinary human being is "the maintenance of an equilibrium always threatened," it behoves the consumptive to regard his own particular equilibrium as very unstable. All of which is plain, but apt to be disregarded as too obvious to be constantly borne in mind.

Concealed Tuberculosis or "The Tired Sickness." A Clinical Study upon the Exhaustion Type of Hidden Tuberculous Infections. By GEORGE DOUGLAS HEAD, B.S., M.D. Philadelphia: P. Blakiston's Son and Co. Pp. 137. $2.00.

THE author of this book has made a discovery. It is that many persons who complain of symptoms commonly traced to neurasthenia are suffering from a tuberculous infection which is the cause of all their troubles. Now, this is a discovery which every intelligent physician makes, and one is inclined to ask: *Why write a book about it?* The gist of the author's thesis is summed up in two of his sentences. "This slow-burning fire of a low-grade tuberculous infection manifests itself in such an insidious manner as to escape detection by the usual clinical methods of diagnosis. . . . This type of tuberculosis fails of recognition *unless the specific tuberculin tests are used.*" There follows a plea for the subcutaneous tuberculin test which the author has never known in his own practice to disseminate tubercle. Yet he has been using Koch's old tuberculin subcutaneously since 1895. Such immunity to tuberculin disasters is extraordinary.

DISORDERS OF THE VENOUS SYSTEM.

Entzündung, Thrombose, Embolie und Metastase im Lichte neuerer Forschung. Von Prof. Dr. PAUL VON BAUMGARTEN, in Dresden. München: J. F. Lehmanns. 1925. Ss. 208. *7s. 7d.*

CONTAINING little in the way of original observations or new conceptions, this book is a compendium of most that has been thought or written on the subject. For such books there is a distinct place, but the usefulness of this particular one will, unfortunately, be somewhat limited for English readers by the author's peculiar style. It may appear presumptuous to criticise the literary construction of a foreign author, but Dr. Baumgarten's habit of including adjectival subclauses within each other surely passes the limits allowable even in the language in which he writes.

DISEASES OF THE EYE IN CHILDREN.

Die Augenerkrankungen des Kindesalters in ihrer Besonderheit. By Dr. L. HEINE, Professor and Director of the University Eye Clinic at Kiel. Berlin: S. Karger. 1925. With nine illustrations. Pp. 52. M.8.

THIS small volume is written for the benefit of those practitioners who, without being eye specialists, possess sufficient skill in the use of the ophthalmoscope to make its employment a routine measure in appropriate cases, and desire to be able to treat all ordinary cases of eye disease in children not requiring operation. Among the useful points that they will find here, and which they would not find in ordinary text-books of children's diseases, are that infants affected with blepharospasm at birth, when the cause has been removed and they can open their eyes, may appear to be completely blind for some weeks, especially in cases of malnutrition. The disease known as kerato-malacia, which is found in badly-nourished infants, is, we are told, extremely rare in Schleswig-Holstein, although in Hesse and Silesia it is not uncommon. With regard to optic atrophy and neuritis, the author tells us very truly that it is by no means easy to make a confident diagnosis in children from a single examination with the ophthalmoscope. In young children the disc may be very pale or grey without the presence of any degree of optic atrophy. On the other hand, cases of apparent or "pseudo-" neuritis are sometimes seen in children when the condition is purely physiological. The author cites a case in which he himself was inclined to diagnose a true neuritis until he discovered the same anomaly in other children of the same family. Most ophthalmic surgeons have had more or less similar experiences. The subject of refraction is only lightly touched on, but what is said is, broadly speaking, sufficient for the practitioner who does not specialise on the eye. We miss any instruction as to special precautions to be taken in the case of myopic children and as to the advice to be given to parents. With this exception the little book is as complete as it can be made in the small space that the author allows himself.

APPLIED ANATOMY.

Sixth edition. By GWILYM G. DAVIS, M.D. Revised by GEORGE P. MÜLLER, M.D. London and Philadelphia: J. B. Lippincott Company. 1925. Pp. 638. 42*s.*

Davis's "Applied Anatomy" has been a well-known and well-studied text-book for many years. The untimely death of Prof. Davis has led to the production of this edition by the present Professor of Clinical Surgery in the University of Pennsylvania. There has been a considerable amount of new matter introduced, and operative descriptions have been brought up to date where required. The illustrations remain a great feature of the book, and some can be termed beautiful. It may be pointed out that the surgeon who, in Fig. 254, is manipulating the right arm of a supine subject, does not seem to be interested in the fact that this limb carries at its extremity a left hand.

The book is beautifully got up, and there is no doubt that it will continue to be a favourite work of reference.

ANTHROPOLOGY.

Measurements, Weights, and Other Facts Relating to Man. By J. F. TOCHER. Edinburgh: Oliver and Boyd. 1924. Pp. 172.

THIS volume of anthropological statistics from Scotland contains the second and third reports of the William Ramsay Henderson Trust. The first, published in 1905, was an anthropometric survey of the inmates of lunatic asylums in Scotland; the object of the Trust in preparing the present volume was to ascertain whether or not the asylum populations could be regarded as fair samples of the general population in this respect. Observations have therefore been made on the population of the north-eastern region of the country and on soldiers drawn from all parts of Scotland. The results obtained show that the insane populations represented the total population very adequately. The volume is essentially one for the specialist; it manifests the elaborate patience and care that all such surveys demand, and will take its place with the similar records that modern biometric schools are steadily producing against the day when there shall be sufficient accumulation to provide a basis for really valuable statistical deductions on a large scale.

Human Constitution. A Consideration of its Relationship to Disease. By GEORGE DRAPER, M.D., Associate in Medicine at Columbia University, New York. London and Philadelphia: W. B. Saunders Company. Illustrated. Pp. 345. 37*s.* 6*d.*

THIS volume is a collection of comprehensive anthropometrical statistics showing the relation between human morphology and disease. Dr. Draper has for some years been collecting data at the Constitution Clinic in the Presbyterian Hospital of New York and has enlisted the help of anthropological and anatomical specialists. He claims that his method is more accurate and more inclusive than those hitherto employed, and that all victims of certain diseases show pronounced morphological features in common. The diseases considered here are gastric and duodenal ulcer, gall-bladder disease, nephritis, hypertension, pernicious anæmia, tuberculosis, and asthma. There is a definite tendency at the present time for workers in all parts of the world to attempt to correlate bodily structure with pathological diatheses. The practical application of such data, if further research confirms the presence of a recognisable correlation, is not yet apparent, but it is easy to speculate on further advances in preventive medicine if it becomes possible to tell from biometric investigation of the school-child or youth what mental or physical aberrations he is likely to develop. This volume must await confirmatory evidence before its value can be appraised.

A Short Course of Physical Anthropology. By M. R. DRENNAN, M.B., F.R.C.S.E., Professor of Anatomy in the University of Cape Town. Cape Town: The S.A. Electric Printing Co., Ltd. 1924. Pp. 43. 5*s.*

THIS little book was written primarily for the students of anatomy of the University of Cape Town, to relieve them from the tedium of note-taking, and its scope "coincides with the limited syllabus which is at present prescribed for the anthropological part of the anatomy course and examination." Prof. Drennan deserves congratulations on the excellent little compilation he has made, wherein a great number of facts and views are given shortly but clearly. The volume can be recommended as a guide or note-book in any department in which a course in physical anthropology is taken, and its modest price puts it well within the reach of students.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The thirty-fifth meeting of the Commission was held in Edinburgh on June 30th, Prof. Alexander Gray in the chair. Evidence as to the provision of dental treatment for insured persons was given by the East of Scotland Dentists Panel, represented by Mr. Ernest Miller and Mr. William Arbuckle. Mr. William Thomson, secretary of the Scottish Coöperative Friendly Society, gave evidence as to the desirability of extending the scope of medical benefit and providing dental and other treatment benefits for insured persons, and also as to various matters in connexion with the administration of benefits by approved societies. Mr. John Reid, representing the chartered accountants of Scotland, gave evidence as to the audit of accounts of approved societies, and urged that this work should be entrusted to chartered accountants in general practice rather than to a special Government audit department. Mr. Matthew Reynard, clerk to the Association of Parish Councils of Scotland and clerk to the Glasgow Parish Council, gave evidence as to the relations between health insurance benefits and Poor-law relief. Mr. T. J. Addley, secretary of the Scottish Professional Assistants' Society, and Mr. R. Williamson, secretary of the Independent United Order of Scottish Mechanics, gave evidence on behalf of the Edinburgh, Leith and District Friendly Societies' Council.—The thirty-sixth meeting was held at the Home Office, Whitehall, on July 2nd, Lord Lawrence of Kingsgate in the chair. Evidence as to the work of the British Social Hygiene Council was given by Mr. E. B. Turner, Dr. Otto May, Dr. P. A. Clements, and Mr. Leonard Bowden. The Cambridgeshire Tuberculosis After-care Association, represented by Dr. P. C. Varrier-Jones and Mr. F. Bunnett, submitted evidence on the need for special benefit arrangements under the Insurance Scheme for persons suffering from tuberculosis. Similar evidence was given on behalf of the London County Council by Mr. G. H. Walmisley. The National Council of Agriculture, represented by Mr. James Donaldson and Mr. Denton Woodhead, gave evidence as to the undesirability of pooling the Insurance funds of societies. Thereafter the Society of Apothecaries, represented by Dr. A. D. Brenchley and Dr. Reginald Wall, and the Association of Certificated Dispensers, represented by Mr. Graham Bott and Mr. A. Wager, gave evidence as to the qualifications of the holders of the Society's certificate for Insurance dispensing. Volume I. of the Minutes of Evidence covering the period from Oct. 10th, 1924, to Jan. 8th, 1925 (the first to twelfth days inclusive), is now on sale at H.M. Stationery Office, price 10*s.* 6*d.* Part II. of the appendix to the minutes, containing the statements submitted by certain approved societies, insurance committees, dental societies, representative bodies, &c., on which the oral examination was based, is also on sale, price 10*s.* 6*d.*

This simple treatment gives relief from pain in Entero-colitis

IN Entero-colitis, where there is pronounced muscular rigidity and pain, an application of Antiphlogistine applied hot and thick over the entire abdominal wall, not only relieves the pain, but proves a valuable adjuvant to internal medication.

The sustained heat of Antiphlogistine produces a depletion of the enteric and peritoneal vessels and stimulates the solar and hypogastric plexuses.

In Entero-colitis, or any affection involving deep-seated structures, the *genuine* Antiphlogistine, by its peculiar property of maintaining a uniform degree of heat upwards to 24 hours, stimulates the cutaneous reflexes, causing a contraction of the deep-seated, and coincidentally, a dilation of the superficial, blood-vessels.

Over 100,000 Physicians use the *genuine* Antiphlogistine—it is the world's most extensively used ethical proprietary.

A NON-TOXIC BACTERICIDE

To those not familiar with the more recent work on scientific disinfection a 'non-toxic bactericide' must appear in the nature of a contradiction in terms; a substance capable of destroying a single cell organism, they argue, must of necessity be harmful to any organism built up of many cells. Even so great an authority as Fränkel has declared that

> **"The ideal purpose, to find an antiseptic which can be used internally, so that it destroys the bacteria within the organism without damaging the same, is certainly unobtainable."**

The mistake in such reasoning, of course, is that it is based on the assumption that the protoplasm of all cells has the same constitution—an assumption which has been shown by Emil Fischer to be not only ill-founded, but wholly fallacious. That this is so, is fully borne out in the convincing clinical evidence of the use of Dimol in the treatment of putrefactive and other bacterial invasions of the intestinal tract, particulars of which will be sent to any practitioner on application to the sole distributing agents:—

THE LANCET.

LONDON: SATURDAY, JULY 11, 1925.

THE STATE OF PUBLIC HEALTH.[1]

THE annual Report for the year 1924 of the Chief Medical Officer to the Ministry of Health, Sir GEORGE NEWMAN, appears this week, being the sixty-seventh of a series presented annually by his predecessors and himself as medical advisers to the Privy Council, the Local Government Board, and the Ministry of Health respectively. The Report follows the precedents of the previous official records, and enables us to get an all-round view of the state of public health in this country, not only for the period covered by the details and statistics, but also in regard to a continuous policy and a progressive planning. The information and advice which it proffers alike to the Ministry and to the local public health authorities include the classified figures required year by year to estimate the state of public health, special references to particular diseases where the circumstances during the year has made them of interest, and notes of investigations undertaken with the object of obtaining fuller knowledge of prevalent scourges. The Intelligence Service of the Ministry now collects and disseminates information from home and foreign sources, and the medical information bureau thus constituted continues to increase in usefulness with the growing accumulation of tested, sifted, and collated experiences. In view of the frequently expressed opinion by semi-scientific speakers and writers that cancer research makes no progress, or that the mystery of cancer lies wholly in some dietetic faults, we recommend our readers to note the nature of the inquiries made already, or now progressing, under the Cancer Committee of the Ministry of Health.

The fundamental data of the physical life and health of the people in England and Wales during 1924 show, as for many previous years, a declining birth-rate, and while this is not balanced by a declining death-rate it is compensated for by the infantile mortality-rate. The death-rate of infants under one year of age per 1000 born during 1924 was 75, a figure which is translated for us in the Report as signifying that during the year in question the country saved 39,000 babies' lives over and above the average annual saving recorded during the decade 1901–1910. The great movement typified by the promoters of Baby Week, the activities of which are noted elsewhere in this issue, is bearing very definite fruit, and the fact that the figures of 1924 do not compare favourably with those of 1923 is an incident accounted for by the attacks of measles. The influence of epidemic infections on the population during 1924 present the special feature that among the mortality-rates there are found exceptional declines under the heading of small-pox, scarlet fever, and enteric fever. But the returns of the notifiable infectious diseases show marked increase of the epidemic disorders of the nervous system, encephalitis lethargica being particularly to blame. Pneumonia also was more prevalent than at any time during the last five years, and many more cases of small-pox occurred, though the mortality-rate was low, as it was in the case of enteric fever. Of these two epidemic inflictions, Sir GEORGE NEWMAN says frankly that, as they are controllable directly or indirectly, "their occurrence in epidemic form is almost culpable." In the year 1924, 3850 cases of small-pox were notified in England and Wales under the Infectious Diseases Notification Acts, and 32 other cases were reported, most of them coming to notice when local outbreaks of the disease were under investigation. Of the notified cases, only 85 were subsequently withdrawn on a revision of diagnosis, showing that with prevalence of the condition ability to detect it becomes much wider spread. Eight of the cases in this large total were fatal, though in Derbyshire alone 1351 cases were notified, and there were 650 cases in Yorkshire, and over 500 and 400 in Nottinghamshire and Northumberland respectively. In the County of London only four cases of small-pox occurred throughout the year, notwithstanding the very large number of persons from all parts of the country who visited the metropolis to attend the British Empire Exhibition at Wembley. Indeed it is one of the most striking features of the disease that London should remain so immune. In connexion with the mildness of the type of small-pox that has been prevalent recently we obtain from Sir GEORGE NEWMAN a clear pronouncement on the policy of making no difference in nomenclature and procedure under the Infectious Diseases Notification Acts as between small-pox and "mild small-pox." He enunciates, as a sound principle, that any specific disease should be notified as that disease, whether the attack be severe or mild.

There is valuable advice to the public in one of the final conclusions of the Report, its gist being that the public should be urged to use existing facilities devised by the Ministry of Health and provided by the medical profession for the maintenance of proper standards of health. Opportunities should never be missed to put before the public the *pressing* need that exists for the coöperation of public action in the promotion of preventive medicine. The columns of the more influential lay papers give this message day by day to enormous constituencies, but that vast progress which might be secured by the employment of medical knowledge and facilities now available is not made sufficiently prominent, and the education of public opinion is not sufficiently orderly. All the figures for the last half century go to prove the success which has attended scientific intervention in overcoming insanitation. This is so far public information that no one is found to-day who would suggest that the money spent in providing a good water-supply or in protecting child-life is other than well spent; and yet in many directions similar opportunities for overcoming disease are neglected. The public does not as yet choose to exercise to the full powers for the prevention of disease which are provided, and criticism of these or scepticism as to their efficacy is not well dealt with. The reasoned arguments of medicine will always be regarded by a certain school of thinkers as the outcome of professional selfishness—that odium we can bear quite lightly; but the reasoned arguments of laymen who speak with justified authority are not sufficiently credited as outweighing inchoate, uninformed or sentimental views—that is a national loss.

X RAY DOSAGE.

THE extensive use of X rays in the treatment of disease has brought about the necessity of measuring the dose administered in terms of a definite unit. A great amount of valuable work has been done at different institutions all over the world in the application of X rays to medicine, but hitherto, on account of the absence of a unit of measurement, it has been impossible to correlate the results and progress has greatly suffered in consequence. Undoubtedly the most urgent need of the radiologist at the present moment is a means of accurately measuring dosage. The first step towards this is the establishment of an X ray unit in terms of which he can compare the results of other investigators with his own. This was emphasised during an interesting discussion on International Units and Standards for X Ray Work, which took place at the International Congress of Radiology held last week at the Central Hall, Westminster—and reported in another part of this issue—when representatives from all parts of the world were present. The subject was considered from the physical as well as the biological aspect. The discussion was opened by Sir WILLIAM BRAGG, F.R.S., chairman of the British X Ray Unit Committee, who dealt with the physical nature of the problem, and he was followed by Dr. BÉCLÈRE, of Paris, who spoke from the standpoint of the radiologist.

Up to the present several units have been employed and confusion is likely to arise if the number of these units is allowed to increase. Already in this connexion the same letter "R" denotes two totally different quantities. Consequently the first step towards the settlement of the problem is to decide upon a definition of the unit which should be universally employed in all countries as a basis for the measurement of dosage. The unit which has found most favour is the electrostatic unit suggested as early as 1908 by the French physicist VILLARD. This unit may be expressed as the quantity of X ray energy which produces an amount of electricity equivalent to one electrostatic unit in passing through one cubic centimetre of air at 18° C. and 760 mm. Hg. Certain factors have to be considered when making this measurement, the chief of these being that all the energy dissipated in the volume of air considered is actually taken into account and that no extraneous effects interfere with the measurement. An absolute unit of this nature has an advantage over other units that have been suggested, in that the dose is independent of the apparatus employed for its measurement. Uniformity of measurement is therefore obtained apart from any particular experimental arrangement. Having fixed upon the unit, the next step is to calibrate in terms of this unit the different instruments employed for measuring dosage. In Germany the above unit has been employed for some time and instruments intended for medical practice have been calibrated at a number of centres situated in different parts of the country. The representatives reported that this scheme had proved quite satisfactory, an X ray dose being reproducible at any time in the various clinics. There are, however, certain precautions to be taken; for instance, it is essential to specify the quality of the radiation, as differences are observed when radiations of different penetrating powers are employed. In practice it has been found necessary to calibrate the instruments for a limited number of radiations of different quality. The establishment of the physical unit and the calibration of the dosimeters fall within the province of the physicist, and they can be carried out to a greater degree of accuracy than is required for practical purposes. Moderate accuracy will suffice, as the measurement of the dose under practical conditions cannot be made with a high degree of precision. The correlation of the indications of the dosimeter and the biological effect is the work of the radiologist. This presents some difficulty because only a fraction of the energy absorbed by the tissue will be biologically active. A good deal of research will have to be done on the biological side to determine this fraction. It is well known that the X rays which are scattered by tissue play an important part in the irradiation of deep-seated cancer. The intensity at a depth shows considerable variation according to the disposition of the apparatus and patient and the experimental conditions at the time of treatment. To obtain any degree of precision, the conditions of irradiation must be carefully stated. For instance, the size of the field irradiated, the voltage of the X ray tube, the distance from and the nature of the target. All these factors—and there may be others—should be noted when measuring dosage. Prof. WINTZ, of Erlangen, emphasised the importance of standardising these conditions so that results may be directly comparable.

To arrive at a complete solution of the problem the radiologist and the physicist must work in close coöperation. Already in this country and in Germany there exist X ray unit committees which have done valuable work in connexion with this all-important question of dosage. It is worthy of note that both these committees arrived quite independently at the same conclusion regarding the adoption of the electrostatic unit. It is likely that several methods will be employed to measure the unit, so that it will be necessary to check the calibration of an instrument in one country against that in another country. It is urged that an X ray unit committee be formed in each country and that these committees should keep in close touch with each other. It was resolved at the close of the discussion at the Congress that an international committee be formed to discuss the matter further, with a view to arriving at a scheme which will be universally adopted. Such an international committee, which will consist of both physicists and radiologists, will perform an important function and, as the result of its deliberations, it is hoped that research on the effect of radiation on human tissue will be greatly facilitated.

THE TASTE FACTOR IN DRINKING WATER.

THE British Waterworks Association held its annual meeting in London last week and discussed various aspects of the water-supply. Sir ALEXANDER HOUSTON, Director of Water Examination to the Metropolitan Water Board, submitted a paper on the Purification of London's Water-Supply. The greater part of his communication was devoted to the problem of taste, since it is insufficient to produce a water bacteriologically safe; consumers expect also to be supplied with a water free from objectionable taste. There are two kinds of taste liable to occur in town waters, chlorinous and iodoform. The former can always be avoided by correct dosage or by de-chlorination, the latter is unaffected by such de-chlorinating agents as sulphurous acid and sulphites. It has been known for a long time that phenol in extremely minute doses reacts with chlorine in water to produce this extremely unpleasant iodoform taste. ADAMS[1] has recently shown that 1 part of phenol in 1000 million parts of water is sufficient to produce taste and that there are sufficient phenol impurities in the atmosphere of towns to supply this proportion. Water authorities using chlorination must therefore protect their water from atmospheric air as well as from fog, mist, rain, and any liquid pollution liable to contain any trace of phenol. In spite of all prophylactic measures, taste troubles may still occur and must be combated. Race, Rideal, Harold, Adams, Houston, and others have devoted much study to this important question. The three chief substances that act as preventors of taste in water are organic matter, potassium permanganate, and ammonium compounds.

---

[1] THE LANCET, May 23rd, 1925, p. 1093.

In the United States and Canada chlorination is nearly always practised after filtration, and it is possible that taste troubles would be avoided by using the chlorine before filtration. Slightly larger doses are required, but the extra expense is almost negligible. During the last eight years 70–80 million gallons of Thames water have been chlorinated daily before filtration, and no complaint of taste has been received from the two million consumers. Potassium permanganate was first used by Houston in 1913 to remove a taste due to *Tabellaria*, and later, with equal success, in connexion with the New River chlorination treatment. The usual dose is 1 in 5 millions, and with waters of surface origin the pink tinge disappears within a few minutes. Unfortunately, however, it persists even with a smaller dose in the case of deep well waters containing hardly any oxidisable matter, thus rendering such treatment practically inadmissible. Permanganate has the advantage that it may be added before, with, or after the chlorine with equally good results. Laboratory experiments seem to show, however, that it cannot be used before filtration if chlorination is to be practised after. Whether or not this is due to the reabsorption of phenol bodies during the filtration process is not known. Ammonia and ammonium compounds are now being used in many places as taste preventers; apparently the first worker to use ammonia on a practical scale was Race. The absence of colour is a great consideration, and although the cost, weight for weight, is higher than permanganate, it may be found on further study that the actual cost is less, since a smaller quantity is required and also it reduces the dose of chlorine necessary for sterilisation purposes. It seems as if ammonia, although it exercises a "*lagging*" effect, ultimately increases the sterilising action of chlorine. The dose of ammonia, expressed as nitrogen, required to prevent taste troubles varies in different cases, but 1 in 5 millions is an average figure. Sir Alexander Houston spoke of an experiment on a large scale, 45 million gallons a day, in which chlorine alone was first used in a dose of 1 in 3 millions. The percentage number of 10 c.cm. positive *B. coli* cultures was 26. When ammonia was added (1 in 5 millions) before the same dose of chlorine, the number of positives was reduced to 4.

The cost per pound of liquid chlorine, liquid sulphurous acid, permanganate, liquid ammonia, and ammonia compounds (expressed as nitrogen) is approximately as follows:—

	Pence.	
Chlorine	2·31	
Sulphurous acid	7·5	
Potassium permanganate	7·0	
Liquid ammon. (liquor ammon. fort.)	11·0	In terms of nitrogen.
Ammonium chloride	11·1	
Ammonium sulphate	9·2	

Thus chlorine is by far the cheapest chemical, and ammonia and its compounds the most expensive. At the same time, if very small doses of ammonia were found to be equally efficient as taste preventers, the balance might be economically in favour of ammonia. It is clear that great progress has been, and is being, made in our knowledge of the reasons why certain waters develop an iodoform taste in the presence of active chlorine, and the best and most economical ways of overcoming these difficulties. One gratifying health feature arises from these considerations. If taste troubles can be economically and certainly overcome, there will be less disposition to cut down the dose, with consequent risk of imperfect sterilisation, in order to avoid complaints from consumers as regards taste. There have been cases where the question of taste rather than of bacteriological result was the dominant factor in determining the dose of chlorine.

◆

CONVENTION OF ENGLISH-SPEAKING OPHTHALMOLOGICAL SOCIETIES.

The convention of ophthalmologists to be held next week in London is to be confined to English-speaking societies, but one of the subjects to be considered at a general meeting is the re-establishment of international ophthalmological gatherings on the pre-war basis. Science knows no frontiers, and it is to be hoped that the promoters of this discussion will be successful in their object. Meantime there is plenty of matter to engage the attention of the convention which is to be opened by a reception at the Royal College of Surgeons on the evening of July 13th. On the 14th, after the formal reception of delegates from the United States, Canada, and Australia, the President, Mr. E. Treacher Collins, will give the opening address on the Elimination of Eye Disease. This will be followed by the reading of papers by various members and in the afternoon by excursions to institutions of ophthalmic interest in London and its vicinity. In the evening a reception will be held at the Royal Institution of Great Britain, at which Sir William Bragg will give an address on Thomas Young and his Work. On the three succeeding days the programme is somewhat similar. Papers will be read during the day. A symposium will be held on the Evolution of Binocular Vision, in which Sir Charles Sherrington, Sir Arthur Keith, Sir Frederick Mott, Prof. G. Elliot Smith, and Prof. S. E. Whitnall will take part; Sir John Parsons will deliver the Bowman Lecture on the Foundations of Vision, and there will be a discussion on the Microscopy of the Living Eye. Sir William and Lady Lister's garden party and a reception at the Wellcome Historical Medical Museum will provide further opportunities for social intercourse, and the proceedings are to be wound up by a banquet at the Guildhall on July 17th, at which H.R.H. the Duke of Connaught is to be the guest of the convention. The organisers are to be congratulated on a programme so full of interest and variety. The meetings are to be held at University College, Gower-street, W.C. 1. On arrival in London every member of the convention is requested to attend as soon as possible at the Registration Bureau.

Bethlem Hospital Site.—*The Select Committee* of the House of Lords which has had before it the Bethlem Hospital Bill authorising the removal of the asylum to the Monks' Orchard Estate on the Kent and Surrey borders, has decided that the measure ought to proceed on the ground that there is general agreement as to the desirability of the scheme. Sir Lynden Macassey, K.C., opposed on behalf of the Southwark Borough Council, which desires to keep the site as an open space, but Mr. Thomas, K.C., for the promoters, pointed out that the charity would suffer if the value of the site could not be realised. The governors were, however, quite prepared to consult with the London County Council and to coöperate with the public authorities.

Annotations.

"Ne quid nimis."

MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEDICAL men who visit the Museum of the Royal College of Surgeons, Lincoln's Inn-fields, will meet with evidence of great activity. During the present month a special exhibition is being given in Room I. of the Museum of all the preparations and donations added to the collection during the past 12 months. At the end of the present month the additions are assigned to their permanent places in the Museum. Of the additions just made, over 300 in number, 170 represent pathological conditions, many of which were obtained by surgeons in the course of operations. Noteworthy are the preparations added to the series which illustrates disorders of the pancreas, for which the College is indebted to Mr. J. A. Cairns Forsyth, and those which exemplify tumours of the testicle, added by Mr. H. R. Dew. Particularly numerous are the preparations which illustrate diseases of bones and disorders of their growth. Visitors have an opportunity of examining the specimens which were prepared by the late Sir William Macewen during his classical researches into bone growth. Specimens presented by Mr. Alan H. Todd show an early stage in the onset of osteogenesis imperfecta. Dr. A. E. Pinniger adds to the collection a heart ruptured by indirect violence. A negro miner, who was within the radius of an accidental explosion, was picked up dead but with no external mark of injury. At the post-mortem examination a rupture was found of the left ventricle. Another remarkable heart was given by Dr. Robert Ellis, of Taunton. It is that of a boy who died from rupture of the ascending aorta, which was the site of an aneurysmal dilatation. Beyond the dilatation was a pronounced stenosis of the aorta of congenital origin. A specimen of identical nature was presented four years ago by Dr. G. A. Sutherland. Another interesting addition is that made by Mr. Arthur H. Crook, of Eastbourne. The preparation represents the viscera of a seventh month child which lived for seven days; it shows a malformation of the lower part of the œsophagus with complete stenosis of the middle part of the duodenum. A gift by Mr. Philip J. Franklin exemplifies a very uncommon malformation—a congenital union of the vocal cords of a child aged 2 years. Lieut.-Colonel R. H. Elliot has added very valuable sections of the eye to illustrate the pathology of glaucoma and of myopia. The same donor has also enriched the series which illustrates the craniology of anthropoid apes, by presenting skulls of the peculiar form of gorilla which inhabits the Kivu forests of East Africa. Through Dr. J. B. Christopherson the College has added to this exhibition specimens prepared by Dr. Fuzinami, of Kyoto, to illustrate experimental schistosomiasis.

The President of the College, Sir John Bland-Sutton, has made donations to all sections of the exhibition now on view. Particularly interesting is a series of models, carved in wood by the curator of the museum of the Historical Society, New Bedford, Mass., to show the external form of the larger kinds of whales. The value of this series is enhanced by an evolutionary tree of the whale family which has been mounted in the same case as the models.

Besides examining the special exhibition, which represents specimens which will be allotted to all departments of the Museum, visitors will have an opportunity of examining other additions and improvements which have been recently made in the Museum of the College. A special case designed by Mr. E. C. Frere, F.R.I.B.A., has been installed in Room I. to contain the surgical instruments and personal mementoes of Lord Lister. The Army Medical Collection is now exhibited in a spacious new room and is available for purposes of study. A special series is being brought together in Room III. to exemplify the various forms of disorder of growth to which the human body is subject. Sir Frank Colyer has set out a remarkable series of specimens to show how repair is carried out in the tusks of elephants after fracture and gunshot injury. Those interested in the portraiture of John Hunter may examine an extremely interesting portrait which, in the opinion of Sir Arthur Keith, is that of the celebrated surgeon, representing him when about his forty-fifth year. This portrait has recently been presented to the College by Mr. G. Buckston Browne. The Museum is open to all medical men and may be visited between 10 A.M. and 5 P.M., except Saturday afternoons, when it is reserved for ambulance and other classes.

THE CHALMERS MEMORIAL GOLD MEDAL.

THIS medal is awarded biennially to persons under 45 years of age for "researches of outstanding merit contributing to our knowledge of tropical medicine and hygiene." At the recent annual general meeting of the Royal Society of Tropical Medicine and Hygiene it was presented by the newly elected President, Dr. Andrew Balfour, C.B., C.M.G., to Prof. Warrington Yorke, of the Liverpool School of Tropical Medicine, in recognition of his work on trypanosomiasis, malaria, and many other subjects. Prof. Yorke read a paper on Further Observations on Malaria Made During Treatment of General Paralysis. The earlier work of Prof. Yorke and Dr. J. W. Scott Macfie on this subject was communicated a year ago and showed that induced malaria, whether as a result of direct inoculation of the blood of an infected patient or the bites of infected mosquitoes, was remarkably susceptible to the action of quinine in a dosage of 30 gr. on three consecutive days. It was further discovered that quinine has no true prophylactic action, for daily doses of 10 gr. of quinine administered for five days before, on the day of and for seven days after the infecting bite of the mosquito, did not prevent the onset of typical malaria. Similarly, 30 gr. given on the day of the bite and on each of the two succeeding days did not prevent malaria. From these results it was evident that quinine, though very efficacious for the primary attack of malaria when parasites appeared in the blood, had no action on the sporozoites injected by the mosquitoes.

Prof. Yorke's paper at this meeting dealt with the subsequent history of the cases reported on last year. The number of relapses has remained at 2 per cent. in more than 100 cases of malaria induced by inoculation of virulent blood and treated by the three-day course of quinine, from one and a half to two and a half years ago. The inoculation of the strain from man to man during three years, involving more than 40 passages, has not produced an increase in virulence or any morphological variation in the parasite itself. Where the infection had been induced by the bites of mosquitoes, with a similar course of treatment, 21 out of 37 patients relapsed, two in the first month, two in the second, one in the third, and the rest from the fourth to the eleventh months. The late development of these relapses is in marked contrast to the experience of the war, when the vast majority of relapses occurred within six weeks of cessation of treatment. Of the 21 relapses, fever disappeared in the majority of cases either spontaneously or as a result of a second short course of quinine. These results are very different from those obtained during the war, and it does not appear that the amount of quinine or the manner of its administration, the period of the year when an infection or treatment occurs, or the strain of parasite can explain this outstanding difference; the only factor which can reasonably account for it is the individuality of the patient. This factor appears to be the one which determines whether a relapse will occur and, if so, when. On the subject of the mechanism of the action of quinine, Prof. Yorke could see no reason to alter the opinions expressed in the communication made last year. Quinine destroys large numbers of the malarial parasites, the broken-down bodies of which act as an antigen to stimulate the production of antibodies which, if present in sufficient amount, bring about a sterilisation of the infection and the cure of the patient. Some evidence has been obtained that the drug acts indirectly in destroying parasites, certain body cells coöperating with the quinine in producing a substance directly toxic to the parasites. The use of large doses and prolonged courses of quinine is not advocated; the best method of treating malaria is to deal with the attack with a few moderate-sized doses and await developments; if relapses occur, repeat the treatment and maintain the general health by diet and avoidance of exhaustion, for relapse depends on the reaction of the patient himself and his capacity to develop immune body.

ANTHROPOLOGY AND PREVENTIVE MEDICINE.

THE fact that certain persons are more liable than others to contract or to succumb to certain diseases must have been known from the earliest days of observation, but the science of immunology is of recent birth and has not yet found an answer to the fundamental question as to why A is happy in immunity while B is not. The facts and experiments concerning racial and species immunity at present recorded form a tangled skein of unrelated and unexplained threads for the unravelling of which the help of the anthropologists is needed. For this reason Lieut.-Colonel J. Cunningham, I.M.S., himself the son of a distinguished anthropologist, chose as the subject of his paper before a recent meeting of the Royal Anthropological Institute "Some Factors in Racial Immunity." India is peculiarly suited for a study of the problems of race immunity since peoples of totally different genealogy, diet, habits, and sanitary standards are there encountered living side by side under identical environmental conditions. Among the observations on record are those of Dr. Agnes Scott on osteomalacia, the incidence of which she found to correspond with the *purdah* system or, in more general terms, with any area where the women live sedentary, secluded, and unhygienic lives. Colonel Cunningham himself has noted the limitation of kala-azar epidemics in Kayalpatnam, S. India, to the Mohammedan community. These, being traders, came in contact with infected towns, but never communicated the disease to the segregated Hindu agriculturists living in the same village. He has also investigated the relation between climatic conditions and dysentery in certain gaols of Southern India. The largest peak in the chart of dysentery incidence was found to correspond with the summer rains, while two lesser peaks indicated relapses occurring at the onset of the hot and cold weather respectively. In fact, the cases of acute attack could be correlated with the sudden changes of temperature accompanying thunderstorms. An example of species immunity is seen in the reaction of rodents to anthrax, the rat being almost immune, the guinea-pig and mouse extremely susceptible, while the rabbit is less so. The racial variation in susceptibility to tuberculosis is strikingly seen in the incidence of the disease in the French Army of occupation, the figures per 1000 being: French 9·5, Moroccans 11·7, Arabs 18·3, Annamites 15·3, and Senegalese 86·1. Modern tests, such as the Calmette and von Pirquet reactions, the Schick test for diphtheria, and the Dick test for scarlet fever, provide an accurate method for estimating natural immunity. On Thursday Island 90·8 *per cent.* of the population were found to be susceptible to diphtheria. Rose Carter has shown that the supposed immunity of the negro to yellow fever is really a case of susceptibility to toxin rather than to micro-organism, so that the death-rate is definitely less among negroes than among white men, although it is doubtful whether the incidence differs greatly.

It has been stated that the European in India is much more liable to intestinal disorders than the native, but 25 per cent. of the natives are infected with dysentery and the apparently greater liability of the white man may be accounted for by his unwitting contact with infected servants. The original claim that native races showed a relative immunity to cancer has been modified in recent years, and the latest statistics tend to show that it is only the particular variety of malignant growth that varies from race to race. The Chinese are especially liable to carcinoma of the stomach and to an epithelioma of the hip, due to sleeping on the hot *K'ang*, and Eastern races generally suffer from a primary carcinoma of the liver that takes the place of Western intestinal cancer. The Javanese show a high percentage of malignancy of liver and uterus. The importance of the factor of exposure to infection, personally or racially, has not yet been adequately assessed. Negro races that have only recently come into contact with civilisation manifest a very high tuberculosis mortality with low morbidity, while those that have been long associated with the white man show figures similar to Western statistics. In Colonel Cunningham's opinion there is no evidence of true racial immunity in man, comparable to that seen in animals, but the coöperation of anthropologists and immunologists is required in the further investigation and interpretation of the facts obtainable.

ICE-CREAM AND SCARLET FEVER.

Dr. A. Mearns Fraser has reported to the Portsmouth Health and Housing Committee on an outbreak of scarlet fever arising from infected ice-cream. Up to the last week in May there was no undue prevalence of scarlet fever in Portsmouth, but on May 29th 21 notifications were received, on May 30th 21, on May 31st 14, on June 1st 8, on June 2nd 9, on June 3rd 1, and on June 4th none. Altogether there were 83 notifications in five days. It was soon noted that the common feature was the consumption a day or two previous to the attack of ice-cream made by a firm of dairymen and sold at various branch shops. On May 30th a medical practitioner notified eight patients who had attended a whist drive and were at first thought to be suffering from food poisoning. They had partaken of ice-cream at the whist drive. Three assistants at the branch dairy shops were among those notified. Ultimately it was found that all the ice-cream was made by a man and a boy at one of the branch shops. The boy went home ill on the night of May 29th and was diagnosed as scarlet fever on May 30th. It was stated that the boy had a sore-throat, which he did not mention, for a week before going off work. Apparently the rash was not noticed until the night of May 29th. There were no cases of scarlet fever among the customers who only consumed milk supplied by the dairy, and after full consideration of the facts Dr. Fraser concludes that the ice-cream was infected by the boy and that none of the other three employees at the other branches was in any way implicated. The dairy firm gave every assistance in the investigation and were quite unaware of the fact that the boy was indisposed during the week previous to his definite attack. The outbreak fortunately was of a mild type. A feature, which has been observed before in the case of milk outbreaks, was the shortness of the incubation period in many of the cases. Another noteworthy feature was the early stage of the illness at which the boy was able to infect the milk. Again, it has been common to a number of other milk epidemics that the symptoms of the apparent infector have frequently been obscure. Dr. Fraser is not aware that scarlet fever outbreaks have ever been traced to ice-cream before, although enteric fever outbreaks from this source are on record. A noteworthy example of the latter occurred a few years ago in the South Shields rural district. The ice-cream in the Portsmouth case was made of cream custard and eggs in an electrically worked freezing machine. The boy's job was to pack the ice-cream into tins for distribution and then take it round to the various branch shops. The outbreak ceased abruptly on the stoppage of the sale of the ice-cream. It is difficult to see how such outbreaks can be entirely prevented. The present one cannot be attributed to negligence, and a daily medical examination of all persons employed in handling milk is hardly feasible.

TREATMENT AT MENTAL HOSPITALS.

RECENT reports of mental hospitals, of which some abstracts appear on another page, show the trend of modern mental treatment in public institutions. There is a steady movement towards treatment as opposed to bare maintenance. Committees and medical officers are realising that the difficulty of restoring the mens sana offers no reason for neglecting to furnish a corpus sanum. Dietaries are everywhere being overhauled to see where they can be improved and their caloric and vitamin content made adequate. Butter is taking the place of margarine and nourishing and palatable items are being added to the menus. Specialist services are being enlisted to remove any source of bodily disability or focus of sepsis, and nearly all mental hospitals now have a dental surgeon attached to the regular staff. The absence of a pathological laboratory is a stigma that every committee is anxious to remove and the research carried on by the expert pathologist should in the long run afford a sound basis for treatment. Perhaps the most important person connected with the mental patient is the nurse, who comes into intimate contact with him in all his moods; in the past the mental nurse has often been drawn from the least trained members of the profession. Now a steadily increasing number are being urged to obtain general training in addition to working for the nursing certificate of the Medico-Psychological Association. The nursing public is beginning to understand that mental nursing is the highest branch of service, demanding gifts which cannot be overestimated. The Commissioners of the Board of Control are urging on mental hospitals the importance of allowing to patients individuality of costume and providing useful occupation in some form of trade or handicraft. A few hospitals have appointed special instructors whose therapeutic as well as financial value is coming to be recognised. There is a growing disinclination to regard mental disorder from its legal aspect. Although at present it is essential for the public and for the doctor that there should be legal safeguards in certain cases, the profession, and the public after them, are beginning to realise that the care of the mentally sick is a purely medical and highly technical matter. The change of opinion is reflected in the fact that in some cases 50 per cent., in others 80 per cent., of the inmates of these institutions are "voluntary boarders," free to leave at 24 hours' notice at any time. It may not be long before 100 per cent. becomes a common record and the certified case is regarded as a slur on the early measures taken. It is realised that mental disease, apart from a small proportion of toxic cases, is a thing of slow development, which leaves time for preventive measures. One superintendent puts biological stress at the head of his list of causation, and such stress is to be recognised and dealt with before the adaptatory functions of the individual have broken down. Another report points out that half of the annual admissions had shown symptoms for more than a year; had competent advice been sought earlier probably few of these would have required certification at all. It is the general practitioner alone who can recognise these early signs and warn the patient or his relatives of the need for care at a time when treatment would be accepted without resistance and breakdown might be averted. Public interest is awakening to the problem of the early mental case, and practitioners must give some thought to the matter if they are not to be found wanting.

AN AMERICAN SMALL-POX EPIDEMIC.

THE Detroit Department of Health has just issued an instructive report on last year's epidemic of small-pox. The rapid growth of this industrial city has attracted a large migratory population which no doubt accounts for the rather high incidence of small-pox in the last ten years. In 1918 there were 893 cases with 6 deaths, in 1920 4 deaths in 1125 cases, but in 1924 a more serious outbreak with 1610 cases and 163 deaths. The high fatality as shown by the following table was largely due to the appearance of hæmorrhagic small-pox.

Case Fatality-rates.

	Cases.	Deaths.	Rate per cent.
Hæmorrhagic ..	124	123	99
Confluent	219	9	4·1
Discrete	441	7	1·6

The names and addresses of contacts being taken usually about midnight, when everyone was at home, provided an exceptionally complete list of those known to have been exposed to contagion. The vaccination history was obtained and the quarantine enforced at the same time. Those exposed to risk could thus be divided into classes according to their vaccination status, and as the subsequent incidence of small-pox is known we have an admirable index of the efficiency of the vaccination shown in the following table:—

—	Exposed to risk.	Number who developed small-pox.	Percentage incidence of small-pox.
Vaccinated within 5 years of exposure	928	0	0
Vaccinated more than 5 years previously ..	1296	27	2·1
Never successfully vaccinated	1350	180	13·3

One table in the report shows the result of exposure according to the type of case to which the contact was exposed and the time of vaccination within the incubation period. The numbers in these classes are small in any case, and as they are expressed merely as numbers and not as rates few conclusions can be drawn. It is worthy of note, however, that 38 persons who were successfully vaccinated within four to eight days from the time of exposure contracted the disease in one form or another. Clearly it is not safe to put off vaccination until one is known to have been in contact with a case. The conclusion which the Health Department of Detroit draws from this experience is that vaccination ought to be compulsory.

AN EAST COAST PORT.

THE annual report of Dr. B. C. Stevens to the Grimsby Port Sanitary Authority gives a good idea of the importance and variety of the medical service of a port. Although no scheduled cases of infectious disease were landed during the year 1924, 38 cases of other disease came under notice, amongst them 18 of influenza. Rats to the number of 1410 were killed in steamers, 1883 in trawlers, 5786 in warehouses and elsewhere about the port; 483 were killed in 12 ships fumigated with sulphur, averaging 41 in each, and 2795 in 91 ships by baits and traps, averaging 31 in each. Of the 9079 killed in ships and port, 543 individuals were black, 8536 brown. Most were killed in May, especially in the warehouses. No remarks are made by the port medical officer on venereal diseases as they affect shipping. Alien passengers, numbering 2219, entered at this port "invariably clean," as the medical officer remarks. Regular inspection of the water tanks of the port led to no complaints. Of 3166 foreign-going craft, 96 were reported to have sanitary defects, and of 238 coasters, 194; 34 sanitary defects were found during 103 inspections of canal boats. 3458 inspections were made of ships and fishing boats; the chief occasion of complaint being dirt: 374 had dirty food lockers, 49 beds were filthy and destroyed (227 others, not so bad, were ordered to be cleaned), 144 ships had dirty fo'c's'les, 70 had dirty or choked w.c.'s, 33 had dirty galleys or cooking utensils, and 3 had dirty forepeaks, being the compartments just below the crew's sleeping-place, which, if dirty, are a nuisance to them. Also 10 ships were verminous. There were some structural defects: 95 decks leaking, 37 defective drinking-water tanks, 69 defects in lighting, defective stoves 30, defective ventilation 27. Fish arriving unfit for food is made into manure; 400 tons of fish were condemned in the year under review along with much other food. The disposal of refuse from fishing boats still causes offence to the town-dwellers, but the gradual rebuilding of the fish market gives tardy hope of betterment. The number and variety of subjects mentioned in this and other reports of the medical officers of port sanitary authorities show clearly how important are their duties. The sailors in the ships are advantaged in comfort and health by criticism of their surroundings if uncleanly or otherwise unhealthy; any defects which may be found are now more readily corrected than they were, and free treatment for venereal disease is available. The public, too, is advantaged by the destruction of unsound imported foodstuffs, while the constant war on rats is but an incident in the unceasing watch against the entry of epidemic or infectious disease from overseas.

ATMOSPHERIC POLLUTION.

The tenth annual report[1] of the Advisory Committee on Atmospheric Pollution covers the period from April, 1923, to March, 1924, and is the largest and most interesting report yet issued. The report deals with various aspects of the central problem, and is divided into eight sections. In Section 1 are given the results of measurement of deposit from the air at different stations, classified according to the amount of deposit, the average monthly values being compared with the previous five years' average and a comparison of summer and winter deposits being made. Out of 28 stations the deposit of tar was lower than the five-year average in 21, higher in 3, and equal to it in 4. Tar is a good indicator of the amount of coal smoke. The insoluble sooty matter was below the average in 18 out of 20 stations, and above it in 11. Section 2 deals with suspended impurity. The results were obtained with the automatic filter, and curves are given for two new stations, Blackburn and Stoke-on-Trent. It is curious to observe the peculiarities of the curves compared, for example, with London, as shown in previous reports. Blackburn shows a double maximum on weekdays, the first about 9 A.M., the second about 11 A.M.; it is significant that the first maximum disappears on Sundays. Comparison between the automatic filter and jet-dust counter indicates a close agreement between these methods: about 10,000 particles per c.cm. correspond with about 0·8 mg. per cubic metre. In Section 3 is given a description of the remarkable darkness which overtook London on Jan. 23rd, 1924. The electric load diagrams reproduced give some idea of the cost to Londoners of a smoke effect of this description. Section 4 deals with the jet-dust counter devised by Dr. J. S. Owens, and a full account is given of the technique in using it. Illustrations show a similarity between mould cells obtained in dust records and cells from dead leaves, indicating a possible source of the cells found in the air. A new form of dust counter is described in Section 6. This is used for the examination of very coarse dust and operates by isolating a column of the air to be tested, allowing the dust to settle and examining the particles which fall upon a known area. Section 7 deals with the dust in the upper air, and sets out the results obtained by Dr. H. H. Kimball, of the U.S. Weather Bureau. The average diameter of dust particles collected at an altitude of 10,000 feet is only a quarter of those in the surface air. In Section 8 an estimate is made of the effect of atmospheric pollution upon visibility. Tests made with a specially designed instrument show a range of transmission through 50 feet of air varying from 99·66 per cent. of the light when the number of suspended particles amounted to 210 per c.cm., to 22·7 per cent. when the number of suspended particles was about 80,000 per c.cm. The report appears at a time when public attention is at last concentrated upon the need for purifying the air, and should be a great incentive to measures directed against atmospheric pollution.

British practitioners can again enjoy unrestricted freedom of practice in Italy. The difficulties of the last 18 months have been adjusted, and the General Medical Council has now been officially informed that the Italian Embassy in London has communicated to all the consular offices under its orders the regulations concerning the admissions of British registered practitioners to the privilege of practising medicine in Italy and its dependencies. The new agreement, which reinstates the reciprocity of 1910, comes into force from the date of its signature (May 21st, 1925) without the need for further ratification or approval.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. W. W. Keir to be Surg. Capt.

W. G. F. Murray, J. G. Maguire, and S. Morrow to be Surg.-Lts.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg.-Lt. Comdr. D. D. F. MacIntyre, T. B. Dixon, and L. S. Ashcroft to be Surg. Comdrs.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. C. G. Thomson retires on account of ill-health.

Capt. R. C. Aitchison retires, receiving a gratuity.

Capt. J. Stephenson, half-pay list, late R.A.M.C., retires on account of ill-health, and is granted the rank of Maj.

MILITIA.

Capt. F. L. Tulloch to be Maj.

TERRITORIAL ARMY.

Maj. C. S. Wink and Capt. W. D. Carruthers resign their commns. and retain their rank.

Capt. R. G. Addenbrooke (late Worcestershire Regt.) to be Lt. and relinquishes the rank of Capt.

Capt. G. M. Brown (late R.A.M.C.) to be Capt.

Capt. A. Angus (late Northumberland Fus.) to be Lt. and relinquishes the rank of Capt.

A. H. G. Down to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. A. L. Taylor, from Active List, to be Capt.

ROYAL AIR FORCE.

Air Commodore D. Munro to be Air Vice Marshal.

INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Col. C. F. Marr.

The Paying Patient.—On July 7th the Queen opened at the Hospital for Women in Soho-square a new ward containing 12 cubicles for patients who will pay from five to seven guineas a week, in addition to fees to physician or surgeon. The Royal Free Hospital will shortly set aside small wards and private rooms for paying patients.

International Red Cross Nursing.—The Duchess of York last week opened the residence for international students which has been provided by the League of Red Cross Societies, at 15, Manchester-square, London, W. The house will provide a home for nurses from all parts of the world who come to take the League's courses, now in their fifth year, and those who have already obtained their certificates are teaching at home what they have learned in England. In addition to the English students the Duchess presented certificates to nurses from New Zealand, Holland, Greece, Norway, Czecho-Slovakia, Latvia, Belgium, Austria, Germany, Switzerland, and Siam.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXX.

THE TREATMENT OF DISSEMINATED SCLEROSIS.

DISSEMINATED sclerosis is an infective disease of the central nervous system, which usually starts between the ages of 15 and 30. In its typical form the disease is characterised by relapses and remissions. This feature is of the utmost importance in diagnosis and can be explained by the invasion, from time to time, of an organism or its toxin into the brain and spinal cord producing an acute inflammatory lesion. This prevents the conduction of nervous impulses through the affected area. Depending on the situation of the "patch," various symptoms will be produced, such as paræsthesia in a hand, weakness of a leg, failure of vision, a "stroke," &c. After a short time the inflammatory process subsides, often without leaving any permanent damage behind it, and this clinically results in a remission. As the onslaughts on the nervous system become more frequent, or intense, irretrievable damage to important conducting pathways in the brain or spinal cord follows, and a permanent disability, such as a paraplegia, results.

The causative organism has not been definitely determined upon, but there is some evidence in favour of the view that the disease is due to a spirochæte, which, however, is not *Spirochæta pallida*. Spirochætes occur in the mouth and intestines of a large number of healthy persons; they are frequently present in diseased tonsils; they exist in the middle ear in many cases of otitis media, and therefore, presumably, may be present in infections involving any of the sinuses which communicate with the nasal passages.

Clinical Forms.

It must be remembered that the classical picture of disseminated sclerosis, as described by Charcot, consisting of intention tremor, scanning speech, and nystagmus, is present, in its entirety, in only about 14 per cent. of cases. The most important part in the investigation of a possible case of disseminated sclerosis is a close inquiry into the previous health of the patient. In a person between the ages of 15 and 30 the occurrence from time to time of symptoms referable to the central nervous system, which appear suddenly and are often accompanied by slight pyrexia, sometimes earning the name of "influenza," and which clear up as a rule within a few days or weeks, should strongly suggest a diagnosis of disseminated sclerosis, provided the Wassermann reaction is negative. These symptoms, which may occur singly, are: temporary diplopia, temporary blindness, paræsthesiæ in one or more limbs, weakness or stiffness in an arm or leg, precipitancy of micturition or actual incontinence, and attacks of vertigo, often with headache.

Further, the rarer manifestations of this disease should not be overlooked. (*a*) Cerebral form, ushered in by a "stroke," usually without loss of consciousness (sometimes a fit, indistinguishable from epilepsy, may complicate the picture), and attended by a hemiplegia, which clears up quite rapidly. Further "strokes" may occur, affecting the limbs on the same or opposite side. In a person under the age of 40, in whom a hemiplegia occurs, if syphilis, cardiovascular disease, and a cerebral tumour can be excluded, disseminated sclerosis should always be thought of as a possible cause. (*b*) A retro-bulbar neuritis, which is due to a patch somewhere in the optic nerve, producing varying degrees of temporary blindness, may be the first sign of the disease. A similar condition may result from an infection of the sphenoidal and posterior ethmoidal cells, and this must be excluded. (*c*) The spinal form of disseminated sclerosis, characterised by a paraplegia without nystagmus, intention tremor, speech defect, or affection of the arms. Such cases must be differentiated from spinal syphilis, spinal cord compression, and subacute combined degeneration of the cord.

On examining a suspected early case, attention should be paid to the presence or absence of the following signs: Nystagmus; pallor of the temporal half of one or both discs; weakness and ataxia of an upper or lower limb, often with some loss of postural sensibility; exaggeration of the deep reflexes on one side or in one limb; a unilateral Babinski, or even an indefinite plantar response; and diminution or absence of the abdominal reflexes, on one or both sides. If no definite physical signs can be elicited the case should not too rapidly be labelled hysterical, but the patient should be requested to report at once should any deviation from health be observed. It is only in this way that an early diagnosis can be made.

A case of disseminated sclerosis is always a long and protracted affair. The doctor should not be misled, as is often the patient, by the natural remissions of the disease, into believing that a particular form of treatment is proving curative. It is necessary to watch the patient closely, for, unfortunately, it may be assumed that a relapse will sooner or later ensue, and patiently to treat symptoms as they occur. Certain general measures can be laid down.

General Measures.

It is of importance to deal at the outset with all possible foci of sepsis. The mouth should be carefully overhauled, and all septic teeth or stumps removed, but this should not be done in an indiscriminate manner, as a relapse may follow, within a few hours, the too drastic clearance of septic stumps. The tonsils, if severely infected, should be removed. In cases which have shown blindness in the initial stages of the disease, an examination of the posterior ethmoidal and sphenoidal sinuses should be made to exclude infection. The optic nerve is separated from these sinuses only by a thin layer of bone, and therefore an infection may readily pass to the optic nerve, as occurs in cases of optic neuritis associated with suppuration in these sinuses. Any middle-ear infection should be dealt with. The general health should be carefully looked after and over-fatigue avoided. Alcohol and tobacco should be indulged in but sparingly. Special attention should be paid to constipation, which often becomes aggravated prior to a relapse.

During a relapse the patient should be confined to bed at least for a week, but preferably longer, and the diet should be light.

Medicinal Treatment.

Arsenic is the drug that has been used for many years past in the treatment of this disease. It can be administered orally in the form of liquor arsenicalis, commencing with 2 minims thrice daily, gradually increasing the dose so that at the end of three weeks the patient is taking 20–30 minims during the day. At the end of four to five weeks the treatment should be stopped, when mercury and iodides may be substituted. Further courses of arsenic should be given with monthly intervals for several years. Incontinence of urine can be helped by the administration of tincture of belladonna. Painful flexor spasms, which may be troublesome in the later stages of the disease, can be alleviated by the use of hot baths or radiant heat and by a single dose of sodium bromide, gr. 15–20, at night.

Special Forms of Treatment.

In practice such treatment, founded on the assumption that a spirochæte is the causal organism in disseminated sclerosis, is sometimes beneficial, and in a few cases seems to arrest the progress of the disease; but as this form of treatment has been under trial for a comparatively short time, it is too early to judge of its permanent effects. Such treatment is only of use in the early stages of the disease before extensive and irreparable destruction of nervous tissue has taken place. A course of six to eight injections of N.A.B. at weekly intervals may be given, the maximum dose not exceeding 0·6 g. Concurrently mercury should be administered either orally (1 drachm of the liq. hydr. perchlor. thrice daily), by inunction (1 drachm daily), or intramuscularly. Potassium iodide, commencing with gr. 15 and increasing to gr. 30, thrice daily, should also be administered. At the end of the course of N.A.B. the mercury and iodide should be stopped for two or three weeks, and during this time an iron mixture may be substituted. The mercury and iodide should then be resumed, and at the end of a further three or four weeks a further course of N.A.B. should be given. Further courses of treatment should follow with suitable intervals.

Various preparations of organic bismuth compounds have been recently investigated in France in the treatment of syphilis and have been found to possess spirillicidal properties only slightly inferior to those of arsenic. These preparations[1] are given intramuscularly into the buttock. In the treatment of disseminated sclerosis they may be used alternately with N.A.B., or may replace this drug should the individual prove hypersensitive to arsenic. A course consists of 10–12 injections, one or two injections being given each week.

Typhoid Vaccine Treatment.—This non-specific form of treatment, probably allied to protein shock, seems to have a favourable effect in some cases in bringing about a remission. A course of about ten intravenous injections of typhoid vaccine are given at an interval of two days. The first dose is 25 millions, and with each subsequent injection the dose is increased, an effort being made to bring about a moderate rise of temperature after each injection. N.A.B. in small doses may be given concurrently at weekly intervals.

Treatment in the Advanced Stages.—In an advanced case with severe paraplegia any treatment can only be palliative, and the special forms of treatment outlined above are, as a rule, contra-indicated. Arsenic should, however, be given by the mouth.

It is not uncommon to find an hysterical element grafted on to the organic paraplegia. This, if recognised, may be removed by means of persuasion, so enabling the patient to use the limbs more than seemed previously possible. The patient should be encouraged to use the affected limbs, and unless in the final stages every effort should be made to prevent him becoming bed-ridden. Massage is of considerable importance, but even more so are a series of active and passive movements. Electrical treatment is rarely called for and may be injurious. Spasticity may be lessened by passive movements and the application of hot baths or radiant heat. Frequently there is a tendency for contractures to develop in the tendo Achillis; a light aluminium shoe should be worn at night in order to prevent this deformity. Re-educative exercises will lessen incoördination and ataxia. A walking chair may be used in order to give the patient confidence.

SOME GENERAL REFLECTIONS ON PUBLIC HEALTH ADMINISTRATION.

BY J. H. L. CUMPSTON, M.D. MELB., D.P.H. LOND.,
DIRECTOR-GENERAL OF HEALTH, COMMONWEALTH OF AUSTRALIA.

I.

DISTRIBUTION OF LEGAL RESPONSIBILITY BETWEEN CENTRAL AND LOCAL AUTHORITIES.

THE extension of civilisation in all communities and the increasing complexity in the relations between adjacent communities has rendered necessary in every country a review of the conditions of local government. The functions of community government are always found to be divisible into:—

(a) Those matters which affect only individual communities;
(b) those matters which affect several immediately adjacent communities;
(c) those matters which affect in common all communities belonging to one nation.

Of these, (a) and (c) are naturally fairly well defined, while (b) is liable to variations arising from topographical, social, or other conditions.

A brief review of the historical evolution will assist to a comprehension of the basic factors which have produced the present status.

England.

England is the original home of the people of each of the countries discussed, and from England each of these communities derived their traditional conceptions of community government. In the historic evolution of the English constitution, after the country had come definitely under one government, this government consisted of a centralised autocracy, which has become modified by increasing stages, until now each local authority has been granted, by concessions from the central authority, a considerable amount of local self-government. There still, however, persists an indication of the centralisation of power in the obligation (often nominal only) resting upon the local authority to secure the approval of the central authority to many executive acts. At first the subdivision of authority between the central government and the local authority was sufficient for all health purposes, and it remains sufficient still in the case of towns and cities which have a population and a revenue sufficient to maintain an adequate health organisation on modern lines. In the country districts however, with scattered populations and smal revenues, but with most of the public health difficulties in miniature, the maintenance of an adequate health organisation is forming a real administrative problem Moreover, the increasing inter-relationships between contiguous local authorities have introduced problems beyond the solution of any individual local authority Consequently, the county administration, embracing often many local authorities, is becoming invested with public health functions to an increasing degree Not only is this so, but the health authorities ar now considering the advisability of grouping togethe small local rural authorities into health districts within counties.

Virginia.

Virginia was colonised by persons holding tenur by royal favour and persons largely respectful o the established constitutional forms of governmen Necessities, however, of the early development o Virginia forced upon the colonists in the differen districts of the colony a larger measure of self-government than was customary at the time in England and in the development of Virginia local self-government has progressed vigorously until the presen condition is that the degree of authority possessed by the local authority is greater than that possessed by the central authority. Consequently, in the large towns the health organisations are as vigorous as, and possibly more vigorous than, the central authority —the State Health Department—but on the other hand the rural districts are very backward and the central authority is now concerning itself with the development of the backward rural communities.

---

[1] Quinby, bismuthyl, and biquinyl are prepared in France: luatol, bismostab, and bismuth metal in England.

Massachusetts.

Massachusetts was founded by the Puritans in a state of fierce revolt against constituted authority, and in the form of government which they adopted for themselves the central authority of any kind was deliberately omitted, a highly individualised form of government being adopted. The same general basis of government exists to-day. Each local community has practically absolute powers of self-government—the central government (the State legislature) being granted further powers only as these are found to be essential to the common good. In health administration it is found that each community is practically a law unto itself, the central authority—the State Department of Health—being largely without power of supervision or direction, and being given power to deal only with functions of government which concern the State as a whole or a number of local authorities in common. It is, however, fully recognised that the modern conditions of social organisation render necessary the endowment of the State authority with greater constitutional powers than it now possesses, and the State Health Department is becoming invested with greater powers, without, however, as yet any recognition of controlling authority over the actions of local authorities. This gradual surrender of power to the central authority—the State Government—can be traced in the form of the existing Massachusetts health laws. The powers and duties of the State Department of Health are specified thus :—

> "The Department shall take cognisance of the interests of life and health among the citizens of the Commonwealth, make sanitary investigations and inquiries relative to the causes of disease, the sources of mortality, and the effects of localities, employments, conditions, and circumstances on the public health. It shall have oversight of inland waters, sources of water-supply, and vaccine institutions. It shall annually examine all main outlets of sewers and drainage of towns of the Commonwealth, and the effect of sewage disposal."

In contrast to this nebulous and indefinite statement of the status of the State Department, the powers of the local authority are thus concisely and comprehensively stated :—

> "Boards of health may make reasonable regulations which shall be published once in a newspaper published in the town. All regulations made hereunder which provide a penalty for violation thereof shall before taking effect be approved by the Attorney-General."

It may be noted that the approval is not to be given by the State Department of Health, but by the Attorney-General.

Notwithstanding this general position which apparently largely secures the independence of the local authority, it has been found necessary from time to time to recognise the domination of the State. This is indicated in two stages by the following related sections of the Health Act :—

> "If small-pox or any other contagious or infectious disease . . . . exists in any place within the Commonwealth the department shall make an investigation thereof, and *shall consult thereon with the local authorities*. It shall have coördinate powers as a board of health, in every town, with the board of health thereof."
>
> "Towns may establish and maintain dental, medical, and health clinics, and in connexion therewith *may conduct* campaigns of general education relative to matters of public health."
>
> "Every city and every town having a population of ten thousand or more *shall establish* and maintain within its limits a dispensary for the discovery, treatment, and supervision of persons afflicted with tuberculosis. Such dispensaries shall be subject to the regulations of the boards of health of the towns and shall be inspected by and be satisfactory to the department."

The complexities of administration thus produced have been one factor in the creation of the intermediate unit, and the law now reads :—

> "The Commissioner shall divide the State into not more than eight health districts."

Each such district has a district health officer who shall act as the representative of the Commissioner with all the powers possessed by the department itself.

It is apparent that Massachusetts from the most extreme form of local self-government has progressed to the creation of district groups for common needs and of State authority for general needs and for unity of authority. The special mention of supervision of water-supply and sewerage may be here indicated as noteworthy.

North Carolina.

In the State of North Carolina, similar in its history to Virginia, the legal public health code gives evidence of the retention of a constitutional form of centralised government, acting at first against a strong tendency to localisation but subsequently going rather to the other extreme and exhibiting an activity on the part of the central authority in matters of detail which are rightly the concern of the local authority. The powers of the central authority—the State Board of Health—are expressed only a little less vaguely than are those of the State Department of Health in Massachusetts, thus :—

> "The Board of Health shall take cognisance of the health interests of the people of the State, shall make sanitary investigations and inquiries, shall investigate the causes of diseases dangerous to the public health, the sources of mortality, the effect of location, employments, and conditions upon the public health . . . . In times of epidemics, the State Board of Health shall have sanitary jurisdiction in all cities and towns not having regularly organised boards of health and are empowered to make all such regulations as they deem necessary to protect the public health, and to enforce them by suitable penalties."

The powers of the local authority, on the other hand, are briefly but decisively and comprehensively expressed :—

> "The County Board of Health shall have the immediate care and responsibility of the health interests of their county. They shall make such rules and regulations as in their judgment may be necessary to protect and advance the public health."

Notwithstanding this central impotence and local autonomy in the basic legislation, it has been found necessary, as in Massachusetts, to give the central authority paramount jurisdiction in all matters relating to sewerage and water-supply, although the abatement of nuisances remains a function of the local authority. There is, however, seen in the North Carolina code a very curious anomaly—the central authority is entrusted with the supervision of all privies :—

> "The State Board of Health, through its officers and inspectors, shall exercise such supervision over the sanitary construction and maintenance of privies as may be necessary to enforce the provisions of this article . . . . the owner of each privy shall pay to the officer or inspector of the State Board of Health . . . . a license fee of forty cents."

The State of North Carolina provides an example of a statutory code in which the predominant power rests with the local authority and also of an administrative organisation in which it has been realised within recent years that the local authorities were not using these powers. In consequence, abrupt transfer of routine detail to the central authority has occurred, supervision of matters of "State-wide" importance, such as water-supply and sewage, has been placed in the hands of the central authority, and an enlightened State administration is now actively concerned in stimulating the local authority by various ingenious devices to a better realisation and a more efficient discharge of its responsibilities.

New York.

The State of New York, cosmopolitan in its history and cosmogenic in its development, provides an example of legal and administrative indefiniteness which conforms to no general rule. The powers of the central authority—the State Public Health Council—are specified as follows:—

"The Public Health Council shall have power to establish sanitary regulations called the Sanitary Code. The Sanitary Code may deal with any matters affecting the security of life or health or the preservation and improvement of public health in the State of New York. The provisions of the Sanitary Code shall have the force and effect of law. No provision of the Sanitary Code shall relate to the City of New York, and every provision of the Sanitary Code shall apply to and be effective in all portions of the State except the City of New York.

"The provisions of the Sanitary Code shall, in the territory prescribed therefor by the Public Health Council, supersede all local ordinances heretofore or hereafter enacted inconsistent therewith.

"Each city, town, or village may enact sanitary regulations not inconsistent with the Sanitary Code established by the Public Health Council.

"Under the public health law, all local health officers have the power, and it is their duty, to carry into effect the provisions of the public health law and the Sanitary Code.

"The State Commissioner of Health, under the same law, has the power, and it is his duty to exercise general supervision over the work of all local health authorities, except in the City of New York, and to see that the provisions of the public health law and the Sanitary Code are enforced."

The status of the local authority as defined in the Sanitary Code is this:—

"The term 'board of health' or 'local board of health' means the local board, department, or Commissioner of Health, or other body or official of a municipality having the usual powers and duties of the board of health of a municipality."

New York State is a striking instance of a State in which the central authority has paramount powers of wide scope. It is very interesting to find that a great deal of public health advancement is being achieved by this State Council without much resort to legal authority, but almost entirely by example, education, and exhortation.

New South Wales.

New South Wales, founded on a basis of necessary military autocracy in which the good of the community was paramount and the welfare of the individual of little account, has gradually throughout the century and a half of its existence evolved a form of government in which the centralisation of authority still persists to a high degree with a slow release of power into the hands of the local authorities. In the existing form of health administration there is still a greater degree of centralisation than exists in the other Australian States. The following paragraph, from the Health Act, 1915, breathes the old spirit of autocracy which is now rapidly disappearing all over the British Empire:—

"The Board (i.e., the State Central Health Authority) may require the council of a municipality or shire or its officers to do any specified acts in relation to any of the matters mentioned in Part I. of the schedule which might lawfully be done by such council or officers in virtue of any power (except the power to make ordinances or by-laws) conferred or of any duty imposed by any statute, regulations, ordinances, or by-laws, and may in such requirement specify the time within which and the manner in which such acts shall be done.

"If such Council or officers fail to carry out any such requirement as aforesaid, the board may do or cause to be done the said acts, and for that purpose shall have the powers of such council or officers; and thereupon the board may demand the payment to it by the council of any expenses incurred by the board in doing the said acts or causing them to be done. Any regulations, ordinances, or by-laws which relate to any of the matters mentioned in Part I. of the schedule shall, before being made, be submitted to the board. Such regulations, ordinances, or by-laws shall not be made unless the board gives its approval of such of the provisions thereof as relate to the matters aforesaid."

The "matters mentioned in Part I. of the schedule" are:—

"Keeping premises free from offensive or unwholesome matter and the suppression of nuisances arising therefrom. Regulating the storage, sale, conveyance, disposal, and delivery of meat, fish, oysters, and crustacea. Regulating cattle intended for slaughter and regulating abattoirs and slaughter-houses. Sewerage and drainage. The removal of nightsoil, filth, refuse, and garbage, and the destruction of garbage. The construction and situation of privies, the regulation of the degree of closet accommodation. Public urinals, closets, and lavatories. The sanitary requirements of public baths, dressing sheds, and dressing rooms. The regulation and control of common lodging-houses and seamen's boarding-houses. The establishment, control, maintenance, and regulation of infants' milk depôts. The regulation of the interment of the dead.

The central health authority, however, is not so entirely independent as the above quotation might suggest. In the Public Health Act of 1902 there occurs this paragraph:—

"The Board may at any time make a report to the Secretary for Public Works whenever, in its opinion, any danger to public health, or to the health of any persons, could be removed or diminished by the exercise by any water-supply and sewerage board of their powers under any Act . . . . and the Secretary for Public Works shall thereupon proceed as he may think fit."

Victoria.

Victoria, dominated in its earliest years by the influence of New South Wales, has undergone development in a different direction. At an early stage in its career certain local communities revolted against the arbitrary exercise of central authority, and there has consequently developed in Victoria a form of government in which the local authorities exercise in practice a considerable degree of self-government. It will be of interest to quote certain sections of the Health Act of the State of Victoria. The specifications of the powers of the central authority—(i.e., the Commission of Public Health) are as follow:—

"In addition to any other powers and duties of the Commission, the Commissioner may exercise all or any of the following duties: (*a*) To promote the prevention, limitation, and suppression of infectious and preventable diseases. (*b*) To report to the Minister upon matters affecting the public health and upon any amendments which it thinks advisable in the law relating thereto and upon matters referred to it by the Minister. (*c*) To promote or carry out researches and investigations and to make inquiries in relation to matters concerning the public health and the prevention of treatment of disease. (*d*) To publish reports, information, and advice concerning the public health, and in particular concerning the prevention and control of disease and the education of the public in the preservation of health. (*e*) To advise and assist councils in regard to matters affecting the public health. (*f*) To prepare regulations under this Act for submission to the Governor-in-Council. (*g*) To prepare model by-laws for adoption by councils pursuant to this Act."

In order to meet any urgent contingency the Commission is invested with special powers:—

"In any emergency or sudden necessity (of the existence of which emergency or necessity the Commission shall be sole and final judge) the Commission may for the purposes of this Act exercise and perform in any part of Victoria all or any of the powers and duties of a council."

To provide for decentralisation of the administrative functions of the Commission provision is made for the appointment of district health officers whose function are defined as follow:—

"Every district health officer shall: (*a*) Be subject to the directions of the chief health officer; (*b*) report quarterly and also annually to the chief health officer on the public health and sanitary circumstances of the health area; (*c*) make to the chief health officer as occasion requires such suggestions as the district health officer thinks desirable for more effectually promoting the objects of this Act; (*d*) advise and assist as he deems fit medical officers of health and inspectors of councils having jurisdiction in the health area and any part thereof; (*e*) exercise such powers and duties to the chief health officer as are assigned to him under this Act by the chief health officer and perform such duties as are required by the Commission or as are prescribed; (*f*) perform such duties in connexion with the medical inspection of and the promotion of the health of school-children as are prescribed."

Notwithstanding that the duties as here prescribed consist largely of supervision of a paternal nature there are definite powers of compulsory direction. For example, the Commissioner may enforce the appointment of a medical officer of health by any council; the Commission may make regulations "generally, carrying into effect the purposes of the Act"; and it has reserve powers of compulsion over any council which fails to discharge any of the duties statutorily prescribed.

While there is in Victoria very extensive local autonomy, there is also comprehensive central direction. This relationship is well-illustrated in the following clause:—

> "Every council (*a*) may, and when required by the Commission shall make or adopt by-laws for all or any of the purposes for or with respect to which such council is authorised or required to make by-laws under the Act; and (*b*) shall when so required by the Commission revoke, rescind, amend, or vary or suspend the operation of any by-law.
>
> "All by-laws made or adopted by a council under this Act: (*a*) shall be submitted to the Commission; (*b*) shall be subject to the approval of the Governor-in-Council; (*c*) may be revoked by order of the Governor-in-Council.

New Zealand.

New Zealand was at first colonised at separate points by communities with little in common, each having a practically independent form of government. Effective central government has only gradually evolved. In 1900 was passed the Health Act, which to a very large degree centralised authority and rendered all health administration practically independent of local authorities; but this was found to be unsatisfactory, and in 1920 the legal health code was revised. Now responsibility in most matters of health administration is placed directly upon local authorities. This basis of local independence, which is at the root of the New Zealand system of government, has led each of the local communities to acknowledge its responsibilities to an extent unfamiliar in Australia, and is the largest factor in producing the advanced state of progress in public health in New Zealand due to this local independence of spirit. It is probably accurate to say that every town of more than 1000 population has a modern water-supply and a modern water-carried system of sewerage. This spirit of local self-reliance has also been an important element in the success of the Plunkett Society in New Zealand.

The Need for Modification of Existing Arrangements.

It is clear that all of these English-speaking countries, with English tradition as a foundation, have evolved towards an increasing local self-government; but the distribution of authority between the central authority and the local authority has taken different forms in different countries. In England there is the nearest approach to administrative regularity with wide powers of local autonomy and general powers of control and supervision by the central authority. But even in England the evolution of the public health system has produced anomalies—the distribution of health functions between the local authority and the county not being such as to satisfy many whose opinion is valuable. Moreover, the equipment and organisation of efficient public health administration to-day are beyond the resources of many of the 649 rural district councils, and the necessity for finding some more satisfactory system of organisation and for expressing such in the legal code is becoming increasingly apparent.

From these examples it is clear that whether health administration started from a centralised autocracy or from localised autonomy, all governmental systems are reaching, by different paths, a type of health administration more or less uniform. The routine local functions, principally control of the environment, are the concern of the local authority, however large or small. The general direction of health policy, a paternal supervision, and the control of matters of common application are the duty of the central authority. It is in relation to the intermediate unit that confusion exists, and an analytical contemplation of the whole field impresses one with the conviction that difficulty mainly arises from the increasing range of matters of individual hygiene constantly being brought within the scope of official public health administration.

A recent survey of many practical attempts to codify this whole problem in legal expression as well as in administrative experiment has confirmed my opinion that a general review of the administrative public health system, at least in English-speaking countries, is overdue. The excessive attention recently paid to matters of individual hygiene, to "campaigns," "demonstrations," and the like, has obscured the necessity for progressive order and good government marching in step with other progress—and legal and administrative confusion is imminent where it has not already occurred. A definition of functions, possibly a modification of both the legal code and the administrative systems, is required, and particularly it is necessary that the diffusion of functions among many authorities shall cease and a logical system of graded responsibility be introduced.

The State of Ohio, U.S.A., claims to have made a practical step towards the reduction of the confusion. Under the old system there were 1300 townships and 700 towns and cities (with a population of 5000 or over) with some sort of county organisation, but this county organisation did not have any health administrative functions. Under the present system there are 86 counties with good health organisation. All of these are doing what the law says they shall do, and many of these are doing in addition what the law says they may do.

The Commonwealth Government in Australia has just appointed a Royal Commission to suggest an organised scheme of rational progress with defined responsibility distributed amongst the different grades of governmental units, and it is expected that great advances will result from the work of this Commission.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(*Continued from p. 37.*)

FRIENDLY SOCIETIES' MEDICAL ALLIANCE.

(App. LIII. and Q. 16346–16513.) The Friendly Societies' Medical Alliance represents the majority of the medical institutions approved under the Insurance Act for giving treatment to insured persons as an alternative to the panel system. The Ministry of Health have always held that they had no power to approve any institution not existing at the date of the passing of the National Insurance Act, 1911.

The principal contention of the Alliance in the evidence given by Mr. S. A. Syddall and Mr. Samuel Pride was that facilities should be provided for the recognition of newly-formed institutions and the extension of the radius of existing institutions throughout industrial districts by the opening of branch surgeries. It was also claimed that as an insured person may change at any time from one doctor's list to another, a similar right of change between an approved institution and an insurance practitioner ought to exist instead of the present arrangement under which an insured person can only change over at half-yearly intervals.

---

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6); Evidence of the Insurance Committees (May 23rd, pp. 1097–8); Evidence of Various Approved Societies (May 30th, pp. 1135–6); Evidence of the British Medical Association (June 6th, pp. 1184–6; June 13th, pp. 1248–50; June 20th, pp. 1316–6); Evidence of other Medical Bodies (June 20th, p. 1316; June 27th, p. 1348); Individual Evidence (June 27th, p. 1348); Medical Services in the Factory, Ministry of Health Inquiry Room, Evidence of National Sailors' and Firemen's Union and of Loyal Order of Ancient Shepherds (July 4th, p. 36).

The total adult membership of these institutions, including insured and uninsured, has declined from 238,000 in 1911 to 100,000 in 1924, and it was pointed out to the witnesses that this hardly appeared to suggest that the institution system was so popular or advantageous to the insured as to justify the case for their extension. The general burden of the evidence so far as this point is concerned seems to be that the institutions had not received fair treatment, and that as they were pioneers in putting something better in the place of the old discredited system of club doctoring and in providing efficient surgery and waiting-room accommodation, they were justified on merits in being more freely established for the treatment of the insured.

In reply to a question as to what an insured person would lose if a partnership or team of doctors were available for him as compared with an institution where three or four doctors were employed, Mr. Pride said that the insured person would lose control.

> (Q. 16163.) We think we have a capital arrangement in our institutions. They are controlled by what are called lay committees, but they are composed practically, to the extent of 60 or 80 per cent., of insured persons, and they have a voice immediately in the direction and policy of the institution. They certainly do not with regard to the panel doctor, and you do not find a great many insured persons on insurance committees.

In regard to the investigation of complaints, the witnesses said that the rules of institutions provided the necessary machinery, but that they were quite prepared to accept the same machinery as that applied to panel doctors.

SOUTH WALES AND MONMOUTHSHIRE ALLIANCE OF MEDICAL AID SOCIETIES.

(App. LV. and Q. 16707–926.) The general purport of this evidence, given by Mr. Walter Conway and Mr. Evan Pugh, was the same as that of the Friendly Societies' Medical Alliance—i.e., that the embargo on the approval of new medical institutions should be removed, and that the administrative and financial conditions under which they work should be revised in their favour. It was also asserted by these witnesses that the insurance committees by their requirements interfered with and hampered the institutions on their voluntary side.

The members of the South Wales institutions are, to a large extent, miners, and under a system of payment of a poundage rate on their wages they secure treatment for their families and put up sufficient funds to cover such things as operations, dentistry, and ophthalmic treatment. The witnesses contended that for systems under which such a comprehensive organised effort was possible there should be every encouragement rather than the hampering conditions which at present obtained. They denied that there was any canvassing for members, and as regards any complaints against a doctor, they said that—

> (Q. 16782.) Instead of the committee taking it up and dealing with it from what may be called the layman's point of view, we always approach the chief medical officer and let him deal with the matter and discuss it from the medical point of view. If there is anything to be said or done we leave it to him to do it.

With regard to the salaries paid, they said that they were willing to compare the amounts paid by the institutions to their doctors with the amounts paid by the doctors themselves to their assistants, and to stand or fall by the comparison.

FRIENDLY SOCIETIES' MEDICAL OFFICERS' UNION.

(App. LIV.; Q. 16514–16706.) This Union was formed to protect the interests of the medical officers of institutions who felt that they were unfairly treated by the Friendly Societies' Medical Alliance. Dr. D. Holmes, Dr. John Roberts, and Dr. A. Hamilton gave evidence. Amongst other recommendations, they asked that medical officers of institutions should be liable to answer personally in any case of complaint to the duly constituted tribunals for panel practitioners, and that the amount of remuneration paid to medical officers for the panel work should be subject to approval by the Ministry of Health.

Their severe criticism of the way in which these institutions were controlled, with two or three exceptions, led a member of the Commission to ask whether it was really consistent on their part to urge the continuance of this system. The reply was that the system needed reforming and that what they wanted especially to get rid of was the lay control. One of the institutions excepted from their strictures was the Coventry Provident Institution, where the doctors have always had a voice in the management.

ASSOCIATION OF APPROVED SOCIETIES.

(App. XLV. and Q. 14251–14500.) This Association represents 150 societies of various types, with a total membership of 1,500,000. Mr. J. E. Hilton, Mr. Robert Smith, and Mr. F. A. Goodwin gave evidence.

Their recommendations in regard to medical benefit included a suggestion that the capitation fee of insured persons who had not selected a doctor should be applied to the provision of specialist and consultant facilities; another proposal was that members incapable of work should be requested to attend morning surgeries and so relieve the evening congestion.

A good deal of the oral evidence was devoted to the suggested merits of the system of payment by attendance over the ordinary capitation system, and of the merits of the Spahlinger treatment for tuberculosis, which the witnesses appeared to consider that the Ministry of Health and the General Medical Council were cold shouldering. Sir Humphry Rolleston said that he was inclined to expostulate against the suggestion that a doctor would not use a remedy to save the life of a patient unless it was guaranteed or authorised by the General Medical Council.

With regard to maternity benefit, it was said that nearly the whole of the cost of maternity benefit has now to be paid to the doctors, leaving the mother with little or nothing to meet other necessary expenses. They therefore advocated that fees payable for attendance by doctor or midwife should be a statutory charge on the general medical fund, and that a fee of £1 1s. be paid, the member being entitled to choose service of midwife or doctor.

STANDING COMMITTEE OF SCOTTISH INSURED WOMEN.

(App. XLVI.; Q. 14501–14602.) The evidence given on behalf of this Committee by Miss Amy Cameron and Miss Margaret Hamilton included the following suggestions:—

1. That definite provision should be made for the payment of sickness benefit to insured women during the four weeks immediately prior to confinement on the production of a medical certificate.
2. That when an insured woman marries, the fact of her marriage should make no difference to her position in insurance, and that she should be entitled to a free year's insurance as in the case of the insured in general.
3. That attendance at a confinement should not be included in medical benefit. It was, in fact, a matter for consideration whether the whole question of provision for maternity should not be dealt with quite apart from the National Health Insurance Act.

The Committee is not in favour of extending medical benefit to the dependants of insured persons on account of the difficulty of proving dependency, and also on the ground that the necessary increase of contributions would be an unfair tax on a very large number of insured women who would never benefit by the extension.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

(App. LVI. and Q. 16927–17126.) Dr. R. A. Lyster, President of the Society, and Dr. J. J. Buchan, of Bradford, said that while the Society fully recognised that much of the improvement in the social and economic and health conditions of the people is the outcome, more or less indirect, of the National Health Insurance scheme, no real attempt has been made so far to attain many of the most important objects of the original scheme. It has become evident that the present system of National Health Insurance suffers great limitations in its possibility for promoting health, and that profound changes are required if the improvement in the health of the people is to continue to be aided and not impeded by it.

The relationship of the work under the National Health Insurance scheme to that done by local authorities should be of a most intimate nature, because (*a*) the work of local authorities in preventing sickness and physical incapacity and ameliorating disease reduces the demands on National Health Insurance; and (*b*) the material assistance and medical treatment provided promotes the general health of the community.

The witnesses suggested that the voluntary groupings of insured persons in approved societies for the purpose of controlling the funds at present available for health insurance is defective and requires regulation and amendment. In regard to insurance committees, the evidence recites:—

> (App. LVI., para 7.) That these committees have certain general public duties, but they have failed to be efficient instruments in the promotion of better health conditions on account of (*a*) the very indefinite character of their duties; (*b*) their very peculiar constitution which results in their being composed, to a considerable extent, of men and women without a sense of responsibility to the public at large; and (*c*) the disregard of a public for a body which has never been representative of them. Insurance committees are, as separate bodies corporate, no longer required. Their duties would be more efficiently carried out by the local health authority.

The present duties of insurance committees in relation to propaganda and education in matters affecting health have been very fitfully carried out, and these duties could with advantage be placed on local authorities. As to maternity benefit, the witnesses thought that the only practical method by which this can be administered in the interests of the mother and child is by requiring local authorities to administer it through their statutory maternity and child welfare committees.

It is the view of the Society that the scope of medical benefit should be greatly extended and its administration transferred to the local authorities; that the advantages of medical benefit as extended should, as far as possible, be made available to the dependants of insured persons, and should also be made available to the poor, the Poor-law medical system being abolished.

For the financing of such an extensive scheme they contemplate that the present Exchequer grant for all services under the Insurance Act should be made available as a nucleus for the enlarged medical service locally administered. The Society believe that medical practitioners should in the future have a direct interest in maintaining the patients' health. Varying payments should, therefore, be made to medical practitioners for work in this direction, the funds for such payments being drawn from any saving resulting from decreased sickness or disablement payments. Up to the present there has been no special inducement for preventive work.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND. At the recent annual meeting of the Fund, held at the Royal College of Physicians of Ireland, Sir William J. Thompson presided. The annual report showed that the amount disbursed in grants, of which there were 80 in the year, was £1755, as compared with £1540 in 1923–24. The increase of the general fund from all sources amounted to £2109 odd, including £142 15*s.* 10*d.* income-tax refunded for two years. Dividends and interest yielded an increased income of £18 19*s.* 2*d.* Subscriptions paid through branches, including those of the Dublin area, showed an increase of £21 9*s.* 6*d.*, while those paid through the central treasurer had increased by £20 5*s.* No legacies were received during the year, and no addition was made to the invested capital of the Fund.

SUMMER SCHOOL OF MATERNITY AND CHILD WELFARE.

THE National Baby Week Council is to be congratulated on the success of its summer school. The proceedings were opened on July 1st by Lord Astor, Chairman of the Council, who read a message from the Queen expressing her warm interest in the movement, and wishing success to the present effort. About 200 delegates from statutory bodies and voluntary societies were present. The method adopted was to have the subject expounded in the first place by various experts and to follow this by a discussion as to how far the views expressed could be utilised for the benefit of the mothers and babies of the country.

The Psychology of Mothers and Children.

Prof. William Brown, Wilde Reader in Mental Philosophy, Oxford, dealt with the foundations of character. He deprecated the tendency, in the present state of our knowledge, to attach exaggerated importance to the action and interaction of the endocrine glands, and explained the principles of psycho-analysis. He pleaded that truth, beauty, and goodness should be rendered attractive to children, that fear and jealousy should be kept out of their education, and that an effort should be made to promote union with the spirit of the universe from the cradle to the grave.

The psychology of the expectant mother was dealt with by Dr. M. D. Eder, of the infant by Dr. Eric Pritchard, of the toddler by Dr. J. A. Hadfield, and of the abnormal child by Dr. A. F. Tredgold. Some of the points made by the various lecturers were: The expectant mother is best helped by allowing her ample leisure for her occupations and work, but when she is in psychological distress an endeavour should be made to arrive at the source of the trouble, or in other words, to make the unconscious motives conscious. The baby has a soul and a personality as soon as it is born, and its mental state should be studied by its reaction to stimuli. For example, intractable crying should be dealt with by investigating the cause of the crying. At the age of 2 a child is full of impulses, for all of which a form of expression must be found; they should never be repressed. Rightly treated the self-willed child becomes the strong-willed man or woman. From 3 to 4 years of age the child begins to learn self-mastery and self-discipline from within by the desire for achievement and the possession of ideals. At first the ideals are acquired from the parents, later they become the child's own. Hence the importance of the behaviour of the parents in order to prevent the acquisition of wrong ideals. The child of weak impulses may be too amenable; the self-willed child who has been crushed may develop into one with a morbid desire to hurt or with a want of self-confidence. The criminal child is one which has acquired, not inherited, wrong ideals. It is better to train a child by giving it a choice than by giving it orders. Children show persistency at a very early age if given liberty and allowed to find something which interests them. A child's achievements should not be praised overmuch. Abnormality in children may be divided into four classes—viz., abnormality in instincts, feelings, intellect, and intelligence. Defects in instinct may interfere with sucking or self-preservation. Combative, acquisitive, and sexual instincts may be exaggerated and another outlet must be found for them; hence the need for more playing grounds. Feelings and the capacity for emotion may be so exaggerated as to swamp the judgment and the control of the consciousness. We have tests for moral perception but not for moral sense. Some people only have a verbal morality and never develop a moral sense. Dull and backward children are a distinct class. The dull, the feeble-minded, the imbeciles, and the idiots are grades of the abnormal. Some children develop functions early (precocious), others late (backward). Some children are backward as a result of illness. Intellect is to be distinguished from intelligence; many people have any amount of learning but are incapable of applying it. At the opening of the discussion Dr. Maria Montessori stressed the importance of *the early years of life, and of endeavouring to bring* the child into social life from the first and not to leave it isolated.

Maternal and Child Psychology at Clinics.

The two practical suggestions which emerged from the discussion were the value of periodical talks at the centres with groups of mothers on the treatment and upbringing of their children, and talks with individual expectant mothers about their moods and mental troubles. Dr. Alice Hutchison, of the Tavistock Clinic and Great Ormond-street Hospital, gave her experience of such monthly talks. When they had special evenings for the talks the attendance was poor; lately they had been more successful by adopting the practice of occasionally closing the clinic early so as to give time for a talk. Dr. Grace Calver related her encouraging experience of talks to expectant mothers. Lady Erleigh pointed out the importance of thoroughly investigating the cause when a child did not fit into its family environment. If a child was persistently naughty, the mother should say to herself, "What is wrong with me?" One speaker thought psychology was an unfortunate word. The general impression seemed to be, however, that it was a convenient word to retain for the use of the workers in the movement, as long as it was clearly understood that it implied "the proper handling of human beings as individuals and not as herds."

The Problem of Maternal Mortality.

The third and fourth days of the School were devoted to the consideration of maternal mortality and morbidity, under the chairmanship of Sir Arthur Newsholme. The subject was ably reviewed at the outset by Dame Janet Campbell, and various aspects of the subject were dealt with by other lecturers. Dr. A. E. Giles spoke on preventive medical measures and Dr. Mabel Brodie (welfare medical officer, Durham County) on the social aspect of preventive measures. Dr. R. A. Lyster dealt with the midwives' part, and the point of view of the medical officer of health was considered broadly in a paper by Prof. E. W. Hope.

In the discussion which followed it was made clearly evident that we have a very long journey to travel before we reach a satisfactory midwifery service for the country. Some of the points emphasised were the quite inadequate instruction in obstetrics received by the medical student, the need for better education of the midwives, and for a great extension of antenatal clinics conducted by medical practitioners with an expert knowledge of obstetrics. Dr. S. G. Moore claimed good results for the voluntary notification of pregnancy in force in Huddersfield. Since 1916 the maternal mortality in childbirth in Huddersfield had been 5·01 per 1000 births, but it had been only 2·50 among the "notified" as compared with 6·18 among the "unnotified." Dr. A. F. G. Spinks (Newcastle-upon-Tyne) was also in favour of the notification of pregnancy. Sir Arthur Newsholme deprecated pessimism and pointed to the improvement since the Midwives Act of 1902 came into operation. He also referred to the mistake made when the administration of maternity benefit was put into the hands of insurance committees instead of into the hands of the sanitary authorities. Dr. Harold Waller was very emphatic in his condemnation of the present haphazard ill-organised midwifery service. He said that there was lack of organisation among the London maternity hospitals. Every borough should have its lying-in hospital beds with a complete obstetrical staff for dealing with in-patients and patients treated at home. The women of this country had forced an unwilling medical profession to take measures to save the lives of infants; they must be prepared to do the same for the sake of the mothers. Dr. Elizabeth Macrory referred to the approaching transfer of the Poor-law hospitals, and suggested that each of these hospitals should have wards allotted to maternity work, staffed by skilled obstetricians, who would conduct antenatal clinics *and act as consultants both to general practitioners* and to midwives. Dr. Dunstan Brewer claimed good results in Swindon from the early investigation, with the coöperation of the practitioner, of puerperal rises of temperature. During the last five years they had had 5000 births in Swindon and no deaths from puerperal sepsis. As a rule, when a rise of temperature occurred during the puerperium doctors and midwives tried to "explain it away," not to explain it. Miss Rosalind Paget put forward suggestions on behalf of the Midwives' Institute: 1. Birth notifications to state the name of the person who actually delivered the patient. 2. A post-mortem to be held on every woman who dies at childbirth. 3. Internal examinations to be made only by medical practitioners or certified midwives. 4. All medical officers of health in dealing with childbirth mortality to be asked to differentiate between doctors' and midwives' cases. 5. Doctors to be asked to employ midwives as maternity nurses. Midwives were feeling the competition caused by the establishment of so many maternity hospitals. 6. The administration and staffing of many maternity homes needs drastic amendment. 7. There is a lack of good consultants for midwives.

CANADIAN PUBLIC HEALTH ASSOCIATION:

THE MILK SITUATION IN CANADA.

(FROM OUR OWN CORRESPONDENT).

AT the fourteenth annual conference of the Canadian Public Health Association, held in Montreal last month for two days, under the chairmanship of Dr. A. Lessard, Director of the Provincial Bureau of Health, Quebec, the subject of infant welfare was discussed in almost all its aspects, but the subject of perhaps the most general interest was the reading and discussion of the report on the milk situation in Canada by a committee of the Canadian Public Health Association. The committee was appointed on Dec. 1st, 1924, to make a study of "milk problems" and to report the findings and recommendations of the committee at the next annual meeting of the Association. The committee named was as follows: Dr. M. M. Seymour (chairman), Regina; Dr. T. A. Starkey, Montreal; Dr. J. A. Amyot, Ottawa; Dr. H. W. Hill, London; Dr. C. J. C. O. Hastings, Toronto; Dr. L. L. Demers, Montreal; Dr. A. J. G. Hood, Montreal; Dr. A. J. Douglas, Winnipeg; Dr. Arthur Wilson, Saskatoon; Dr. F. T. Underhill, Vancouver; and Dr. R. H. Murray (secretary), Regina. All the members of the committee are provincial and city health officers, with the exception of the secretary and Dr. Starkey, professor of hygiene, McGill University. Among the various points of interest in the report it may be noted that the average consumption of 21 Canadian towns which have reported on this feature of the supply showed a per capita consumption of 0·71 pint per day. The per capita consumption of the city of New York in 1923 was 0·54 pint per day. While statistics regarding the relationship of disease to milk in Canada are largely lacking, the report states that the fact remains that milk has been the means of causing more disease than any other single food, and consider it as much the duty of the local health authority to safeguard the milk-supply as it is their responsibility to provide a safe water-supply for the citizens.

Pasteurisation.

Perhaps the most instructive part of the report is that which refers to pasteurisation of milk. In

Canada, with the exception of Quebec, Vancouver, and Victoria, all the larger Canadian cities and towns are in favour of compulsory pasteurisation, and the Provincial Health Departments of Quebec, Ontario, and British Columbia have declared their belief in the efficacy of this mode of dealing with milk. However, it is pointed out that, while theoretically it is most desirable that all milk offered for sale to the public be pasteurised, it is difficult, and in fact practically impossible, to carry on pasteurisation as it should be done in communities with populations of less than 5000. The point is emphasised that any attempt at commercial or unscientific pasteurisation is worse than no pasteurisation, inasmuch as it tends to create a false sense of security on the part of the consumer. According to this report, the consensus of public opinion to-day is that the milk supplied to all urban centres should be pasteurised. But if a city or town is not sufficiently large to warrant the establishment of a modern pasteurising plant, other means must be found to protect the supply or to provide such a plant. It is the opinion of members of the committee that the public must be educated to appreciate the necessity for pasteurisation of milk-supplies, and the question is how the public is to be educated. Various suggestions are made.

Education of the Public.

It would appear, says the report, that the first step towards introducing successfully any sanitary reform in Canadian communities is not so much the education of the public as the education of the medical profession, by whom the public still seem to be guided in such matters, rather than by public health officials. Therefore the committee recommend intensive and continuous propaganda in this direction by every available agency. Testing of herds by tuberculin is recommended for rural districts, although the committee state that it must be clearly understood that tuberculin testing is not an efficient substitute for pasteurisation, and public health authorities must seek to correct the idea which is growing in the public mind in Canada that pasteurisation and tuberculin testing are alternative methods of protecting milk-supplies. The vexed question of certified milk is reported on by the committee, but the matter appears to be in so confused a state that no reliable data are forthcoming, and consequently no definite statements are made. The question, too, of inspection and laboratory control in Canada is unsatisfactory. The report says: "It is doubtful if there is any municipality in Canada with a population of less than 3000 which has a trained dairy inspector to protect the milk-supply."

Conclusions of the Committee.

The conclusions of the committee are that pasteurisation of milk should be encouraged by every practicable means. The following standardised definition for pasteurised milk is recommended by the committee for use throughout Canada: "Pasteurised milk is milk which has been heated to a temperature of not less than 142° F. and not more than 145° F., kept at such temperature for not less than 30 minutes, and then immediately cooled to a temperature of 50° F., and kept at or below this temperature until delivered to the consumer." The committee contend that safeguarding the milk-supply is as much the duty of a municipality as safeguarding the water-supply, and in view of the efficacy of pasteurisation, in their opinion, in preventing outbreaks of milk-borne disease in large centres of population, they hold that municipal authorities should provide and work pasteurisation plants for the benefit of the dwellers in municipalities. This milk report is a valuable and lengthy document, which is well worthy of a close consideration. Its salient feature is its whole-hearted advocacy of pasteurisation, when scientifically carried out, which seems to be regarded by the members of the committee as the only really reliable practicable means at present known of ensuring a fairly pure milk and of warding off disease by the agency of milk.

Among those who read papers at the conference and took part in the discussions on the various matters were Dr. Helen McMurchy, chief of the Division of Child Welfare, Department of Health of Canada; Dr. A. B. Chandler, Child Welfare Association, Montreal; Prof. Raoul Masson, University of Montreal; Hon. Dr. W. F. Roberts, Minister of Health for New Brunswick; Dr. Eugene Gagnon and Dr. A. Plante, Child Hygiene Division, City Health Department, Montreal; Dr. John W. S. McCullough, chief officer of health for Ontario; and Prof. J. G. Fitzgerald, University of Toronto.

Public Health Services.

SCHOOL MEDICAL SERVICE.

STATISTICS from two school medical reports for 1924 are given in the following table:—

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Nottingham ..	41,349	37,690	12,204	37,600	13·5
Sheffield.. ..	81,197	72,416	23,485	107,494	17·5

* Excluding dental defects and uncleanliness.

Nottingham.

School medical officers generally will support Dr. E. M. Wyche in his plea for a quiet, well-lighted, warmed, and well-ventilated room in which to examine school-children. The conditions at present under which such examinations take place in nearly all areas are crude and often necessitate a further examination at some distant clinic, entailing a loss of time for the doctor, nurse, and parent as well as a loss of school attendance for the child. Dr. Wyche discusses practically all the scheduled defects and points the way to ameliorate or even eradicate much of the present morbidity. Hypermetropia being the normal condition in childhood will always be with us, but myopia can to a certain extent be checked by early recognition and treatment followed by sound and sensible school hygiene. Defective dentition often takes its origin in the malnutrition of the mother prior to the birth of the child, so prophylaxis starts with the maternity and child welfare scheme. Mr. H. B. Tawse, the aural surgeon, stresses the necessity of early recognition and treatment of morbid throat and nose conditions which can be done by fully coördinating the welfare services with the school work. The altered attitude of the parents towards remedial methods is all to the good. The Board of Education have shown their appreciation of the work already done in Nottingham by appointing it one of the centres for investigating the causes of enlarged tonsils and adenoids.

Statistical evidence of the progressive value of the school medical work is evidenced in comparative tables for the past few years. Uncleanliness has diminished from 15 per cent. in 1921 to 13·3 per cent. in 1924, tonsils and adenoids from 11·9 per cent. in 1918 to 3·5 per cent., ringworm from 725 cases in 1913 to 207 cases in 1924. Dental defects are now 55 per cent. as against 75·6 per cent. in 1918. Scabies and impetigo, the fellows of dirt and neglect, are rapidly diminishing coincident with an increase of self-respect and well-being which go with cleanly and healthy habits.

A new open-air school with accommodation for 140, and up to date in every respect, is now to be added to those already in existence; this will spread the gospel of fresh air and sunlight and bring happiness, health, and vigour to many ailing children. The education committee are now considering the question of supplying an ultra-violet rays machine to augment the work of the open-air schools. The success of a camping holiday during August, 1924, which enabled 209 boys to enjoy the "jolliest week of their lives," has prompted Dr. Wyche to submit to his committee that such a camp be organised every year for a period longer than a month with a proper educational curriculum and that girls should benefit equally with the boys. In an inquiry undertaken by Dr. Wyche and the senior assistant, Dr. A. A. Newth, they found that the average educational gain in one year for dull and backward children taught in special classes was 11·9 months—a very favourable result when we remember that the normal child may be expected to advance educationally 12 months in each year. Averaging results amongst small numbers scarcely gives conclusive proofs, nevertheless the increase in educational attainments amongst individually taught dull and backward children distinguished them from definite mental defectives with whom no such results are obtainable. Tribute is paid to the loyal and helpful coöperation of the teachers, attendance officers, and many voluntary bodies by whose aid much remedial work has been made possible.

Sheffield.

The report of Dr. T. Chetwood contains a large number of interesting points usually summarised in a few concise sentences. The general characteristics of the area seem to be expanding work well carried out with a barely adequate staff and a need for the further extension of institutions like the clinics. The percentage of defects found is only slightly below the average, while the percentage treated (95 per cent.) is strikingly above that of previous years (e.g., 67 per cent. in 1914) and is hardly to be improved upon. The only treatment where efficiency is open to any doubt is that of nose and ear conditions for which no clinic is provided by the authority. A line or two in the introduction gives the welcome information that a local medical committee which is studying epidemic encephalitis has the school medical officer as a member. On this subject the school medical service can contribute greatly to general medical knowledge.

A brief but authoritative account of some special observations shows that in nutrition and weight the Sheffield children are now below the pre-war standard. This is the case in some but not all other areas, and it may be related to the circumstance that Sheffield has more than its fair share of unemployment. Defective vision receives some significant comments, such as the reference to its much greater frequency in secondary schools and the influence of homework.

A special investigation was conducted on the incidence of squint following measles. This was found to have occurred in 53 out of 1978 cases, or roughly 2·7 per cent. The interest was not merely statistical, for the majority of cases received the early treatment that is so essential. Another matter which has not attracted as much attention as it deserves was the condition of spectacles. A sample of boys in a poor school who should have been wearing glasses were seen monthly by Dr. J. H. Campain for six months. It was found that only 48·6 per cent. were wearing satisfactory glasses at every monthly examination, and from our own experience we do not think that these results are very exceptional especially when there are included the instances of glasses bent so as to interfere seriously with the optical centring. Reluctant as we are to suggest fresh burdens for the teachers or nurses, we think that the results of a periodic roll call of spectacle-wearers would amply repay the loss of a few moments' time.

Among infectious diseases chicken-pox has called for more notice than usual owing to the prevalence of modified small-pox in areas bordering on the city. The dental work is unfortunately limited by the somewhat inadequate numbers of dentists, but within the limitations the subject seems to be energetically pursued, with some special attempts to enlighten ignorant parents. At the skin clinic there is noted a very marked diminution of ringworm of a generalised type, attributed to the early diagnosis by the school doctors, nurses, and still more important by the mothers of the children. Special schools are mentioned but seem to contain few children over 14; it will be a great advantage when the promised new school for mentally defective elder boys is set up. Elsewhere this has been found to be a valuable type of school giving the boys stability of character, increase of self-respect, and habits of industry. It is satisfactory to see that dull and backward children are regarded as within the province of the S.M.O.; not only is it his duty to separate them sharply from the mentally defective, but in many cases there are minor defects of the nervous system, sense organs, and the like, which need his special attention.

In conclusion, Dr. Chetwood modestly calls his report imperfect and incomplete. With this statement we are unable to agree. We might wish the report had been longer, but it is certainly not lacking in interest and real value.

MENTAL HOSPITALS SERVICE.

THE annual report of the *East Sussex* County Mental Hospital at *Hellingly* includes the reports of the visiting committee, resident physician, dental surgeon, resident engineer and surveyor, the commissioner of the Board of Control, and the various visiting committees of the guardians and other public bodies concerned with the institution. It concludes with statistical tables showing the movement of the asylum population, the recovery- and death-rate, ætiological factors, and the forms of mental disorder. A visiting ophthalmic surgeon has been appointed, an operating theatre is projected, and it is the intention of the committee to appoint a whole-time pathologist with a trained assistant. The latter is particularly needed for work in connexion with asylum dysentery, which is still a troublesome feature, although the number of cases has diminished during the past year. Apart from a small epidemic of mumps, the staff are able to congratulate themselves on an entire freedom from zymotic disease. The medical superintendent points out the large number of senile cases admitted. The attention of the guardians has already been drawn to the desirability of providing the custodial care, which is all that is required for such people, in the workhouses, thus rendering the patients much happier and leaving the mental hospital accommodation free for recoverable cases. Dr. F. R. P. Taylor gives an interesting table showing the desirability of placing mental patients under treatment as early as possible. This aspect of the work is represented by the attendance of Dr. Taylor at the clinic for nervous disorders at the Princess Alice Memorial Hospital in Eastbourne, although it is desirable that this valuable clinic should reach patients over a wider area of the county than at present. The asylum itself is able to show a satisfactory recovery-rate of 33 per cent. for the males and 42 per cent. for the females. The death-rate, also, reached a record of only 6·6 per cent. in the year. The dietary scale has been revised in a careful and ingenious way, so as to allow ample variety of food without increase in cost. It is satisfactory to note that an increasing proportion of the nursing staff are equipping themselves with the nursing certificate of the Medico-Psychological Association, and the committee has decided to appoint a sister-tutor to aid them in their studies.

The *Cumberland and Westmorland* Mental Hospital is unique in that the greater proportion of its 800 patients are male. This is partly accounted for by the conditions of population, but seems an interesting point that might repay further investigation. The number of admissions during the past year dropped to the lowest on record; most of those were hopeless cases and many of them senile. Nevertheless, a recovery-rate of 42·7 per cent. is recorded—a good figure under the circumstances. The hospital has been free from all epidemic diseases except influenza. The parole system is used with much success as a preliminary to discharge.

The *Cheshire* Mental Hospital at *Parkside* reports a successful year of work with a death-rate of only 6·2 per cent., in spite of epidemics of influenza and some sporadic cases of dysentery and tuberculosis. A particular feature of this hospital is the occupational therapy, which is under the charge of a special worker, and includes all kinds of healthful and useful activities, organised games, drill, raffia-work, rug-making, and so on. 77 patients have been instructed in some kind of handicraft during the year, and the value of such stimulus in the treatment of mental disease is indisputable. 136 male and 60 female patients have been allowed out on parole, and advance has been made in the employment of open-air and hydrotherapeutic methods. Since the publication of the report arc lamps for artificial sunlight treatment have been installed, and new verandahs provided to the wards. In the laboratory a routine investigation of the endocrine system is in progress, and also research on the superficial vascular system and its reactions in mental disease. Several of the nurses have been allowed leave in order to undergo two years' training in general nursing, an experience which must very considerably increase their efficiency as mental nurses. Female nurses have been successfully employed in the sick-wards on the male side. The report includes a note by the chaplain, who pays a tribute to the devotion and patience of the nursing staff. It is clear that Cheshire may congratulate itself on having one of the most progressive mental hospitals in the country.

The *County Borough of Middlesbrough* maintains some 450 patients in its mental hospital; 60 per cent. of these are usefully employed, and parole and day-leave are used as freely as possible before discharge. The institution has been free from dysentery and enteric fever, and has suffered only from the universal influenza. There is at present no dental surgeon, a defect that will, no doubt, be soon remedied. The recovery-rate reaches the figure of 41·7 per cent. and the death-rate 8·4 per cent. At present the work is somewhat handicapped by the need for a pathological laboratory and for an admission ward, in order that new cases may not have to associate with old and incurable patients.

The *City of Leicester* maintains an excellent mental hospital for 900 patients at *West Humberstone*. The year's work has been as successful as such work can ever be, with a recovery-rate of 44·5 per cent. and a death-rate of 6·7 per cent. There has been complete freedom from tuberculosis and zymotic disease. 77 per cent. of the patients are usefully employed, and every variety of entertainment is provided for them. They run a quarterly journal of their own without assistance; 20 per cent. of them wear their own clothes, and the garments provided by the institution show a refreshing individuality in cut and pattern. It has been found possible to allow 40 per cent. out on parole or leave, and only four cases have abused this privilege. A visiting dentist has been in attendance for two years, and is on a fair way to achieving his ideal of clean mouths in all patients. The malarial treatment of general paralysis has resulted in recovery and discharge in 21·7 per cent. and marked improvement in a further 13 per cent. The medical superintendent places biological stress first of all the causes of mental disease, followed by heredity, syphilis, and epilepsy. It is interesting to note that the ratio of insanity to the population of the town is now only 1 : 331, whereas ten years ago it was 1 : 320.

The *County and City of Worcester* Mental Hospital at *Powick* supports 1000 patients. The death-rate during the past year has been 7·58 per cent., partly owing to an epidemic of influenza. The nurses are encouraged to work for the certificate of the Medico-Psychological Association. Parole has been granted to some male patients. The report includes notes by the Anglican and Roman Catholic chaplains, and some interesting statistical tables showing the movement of the hospital populations, the discharges, recoveries and transfers, and causes of death.

The *Glasgow* Royal Asylum presents its 111th report for the year 1924. Its age has not debarred it from keeping abreast with all modern advances in the treatment of mental cases. Voluntary boarders are steadily on the increase and now constitute 50 per cent. of the inmates. Occupational therapy is being extended as rapidly as possible under a skilled instructress, the aim being to make the patients self-supporting. The patients are taking great interest in the work, which includes all kinds of handicrafts, such as chair-covering, basket-making, china-painting, rug-making, &c., and necessitates a sale twice yearly to dispose of the products. A nursing home for incipient cases has been established, and the physician-superintendent urges the need for further coöperation between the profession and public, and education of the latter in the problems of mental disease. Forty-four out of 118 cases admitted had had symptoms for over a year before seeking skilled treatment; the importance of out-patient work, social service, and home care is not yet adequately realised. In Dr. D. K. Henderson's opinion there should be wards for acute mental cases in all general hospitals. The pathological side of the work is looked after in the Western Asylums Laboratory, where research is being conducted on the influence of toxic factors in mental disease, and the effect of combined protein shock and arsenic in general paralysis.

The second report of the *Inspectors of Lunatics for Northern Ireland* is for the year 1923, and deals with 4000 patients in the various asylums of the country. The death-rate has fallen to 8·3 per cent., from the high figure of 12·3 per cent. recorded for 1922. At Antrim it has been found possible to employ an increasing number of inmates, but the staff are not yet adequately trained. Belfast, in common with several English mental hospitals, has tried the experiment of using female nurses in male wards, and is satisfied with their success. Londonderry is handicapped by old and inadequate buildings, and has a death-rate of 10 per cent. The voluntary boarder system does not yet seem to have been adopted in Ireland. The report contains valuable statistics of the causative factors, causes of death, cost of maintenance, &c.

The annual report of the *City of Cardiff* Mental Hospital contains statistical tables, the reports of the visiting committee, medical superintendent and commissioner, and a list of the original papers published by the officers of the institution. An interesting feature of the medical report is the inclusion of observations by the various research workers on the experiments they have conducted. A large series of blood-sugar estimations has been carried out in epileptics and paralytics, and a report has been made to the Medical Research Council on this subject. The effect of adrenalin and of adrenalin with thyroid or thyroxin on the blood-sugar of rabbits has also been studied. The therapeutic effects of tryparsamide were investigated in four cases of dementia paralytica. The examination of gastric digestion in early and recent cases has been continued, and a large number of routine tests have been performed. The estimation of phosphorus and calcium in blood and cerebro-spinal fluid has led to the evolution of a procedure which estimates phosphorus with an error of not more than 5 per cent. The Boltz test is being applied, and seems likely to prove a simple and satisfactory method of diagnosing neuro-syphilis. The treatment of epilepsy by luminal and dialacetin has proved satisfactory. A gynæcologist and rhinologist have been appointed to the staff, and the consulting dentist has made over 500 examinations. There are well-equipped radiographic and hydrotherapeutic departments. The out-patient clinic at the Royal Infirmary is continuing its work, but is handicapped by the lack of any in-patient accommodation. A sister-tutor has been appointed and the control of the male wards has been placed in the hands of the matron.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 27TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 68; scarlet fever 1315; diphtheria, 700; enteric fever, 50; pneumonia, 937; puerperal fever, 20; cerebro-spinal fever, 5; acute poliomyelitis, 1; acute polio-encephalitis, 1; encephalitis lethargica, 19; dysentery, 6; ophthalmia neonatorum, 116. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 93 from measles, 9 from scarlet fever, 58 from whooping-cough, 21 from diphtheria, and 23 from influenza. In London itself the deaths from influenza numbered 2, from whooping-cough 12, and from diphtheria 5.

Obituary.

THOMAS MARK HOVELL, F.R.C.S. EDIN.,

CONSULTING AURAL SURGEON, THE LONDON HOSPITAL.

WE have already announced the death of Mr. Mark Hovell, the well-known laryngologist, which occurred on July 1st at the house of a relative in Ipswich after a somewhat protracted illness.

Thomas Mark Hovell was born in 1853, but until recently his youthful appearance and active manner belied his age. He was the son of Mr. Dennis de Berdt Hovell, a well-known practitioner in the north of London, and in his day President of the Clinical Society. His mother was Mary de Horne, who came of an old Flemish Quaker family, and on both sides he was able to trace an unusually long pedigree. He was the second child in a family of ten, and inherited the family property. He received his education at Guildford Grammar School and later at the medical school of the London Hospital, qualifying as M.R.C.S. in 1875 and taking later the F.R.C.S. of Edinburgh. He decided early in his career to take up the subject of diseases of the nose, throat, and ear, at that time fairly new as a definite specialty, and was elected surgeon to the Golden Square Hospital as quite a young man. At this hospital the leading spirit was Sir Morell Mackenzie, who, in 1887, took charge of the German Crown Prince, later the Emperor Frederick III. of Germany, whose throat symptoms were already causing great anxiety. This anxiety, in the political circumstances of the time, was shared by the whole world, and the circumstances imparted into the treatment of the Crown Prince a most unhappy element of fierce quarrelling. There is no need to recall the acrimonious differences of opinion which manifested themselves between the patient's medical attendants during the various stages of a disease which ultimately proved fatal. In those disputes Hovell was only implicated in a secondary position, when he accepted Mackenzie's invitation to take resident charge of the distinguished patient, whom he accompanied to San Remo and later to Berlin, where he was in daily and hourly attendance until the end came in the summer of 1888. His records of the progressive condition formed the clinical history of the case, but their evidence, as far as they proved the contentions one way or the other of those who disputed both the diagnosis and the treatment, he left for evaluation to the protagonists in the dispute. He took little or no part in the arguments, but the skill and sympathy with which he discharged his duties as resident surgeon were admitted on all sides, and were specially acknowledged by the patient who conferred upon Hovell the German Order of the Crown immediately upon his accession to the throne.

Upon his return to England Hovell was appointed lecturer on diseases of the throat at the London Hospital, was regularly attached to the staff of the hospital for many years as aural surgeon, and was appointed consulting surgeon at the expiration of his active functions. He was also consulting surgeon to the Golden Square Hospital, and wrote out of his wide personal experiences a treatise on diseases of the ear and naso-pharynx, which was a standard work for many years. He acquired a large consulting practice and his advice was much valued by practitioners, who saw in him a man of much and varied personal experience. In private life he was the kindest and most hospitable of men.

Outside his medical work he conducted for many years an intensive inquiry into the manners of rats. His book "Rats and How to Destroy Them," which was published last year, is a record of patient study extending over some 30 years, and reveals an intimate knowledge of the habits of rats in most conceivable circumstances, showing also how in each particular their persistent assaults can be defeated.

Mr. Mark Hovell married in 1905 the Hon. Margaret Bateman-Hanbury, a daughter of the second Lord Bateman, by whom he had one son.

CHARLES FORBES HARFORD, M.D. CAMB.

Dr. C. F. Harford, the founder and first Principal of Livingstone College, Leyton, died suddenly on July 4th at his residence in Harpenden, aged 60. The youngest son of the late Canon Harford-Battersby, Charles Harford was educated at Repton and Trinity College, Cambridge, and studied medicine at St. Thomas's Hospital, London. He obtained the M.R.C.S. and L.R.C.P. in 1889, and graduated M.B., Ch.B. Camb. in the same year, gaining the M.D. in 1892. On qualifying Dr. Harford went as a medical missionary of the Church Missionary Society to Lokoja, West Africa, returning in 1893 to found the College that offers a training in the elements of hygiene to missionaries before leaving the country. In medicine he devoted himself particularly to the specialty of ophthalmology, and at one time held the posts of ophthalmic assistant at St. Thomas's Hospital and at the Royal London Ophthalmic Hospital. During the war he acted as ophthalmic specialist, holding the rank of Captain in the Royal Army Medical Corps, and subsequently gave his services in that capacity to the Ministry of Pensions, Chelsea. At the time of his death he was refraction assistant at St. Bartholomew's Hospital and oculist to the school clinics of the London County Council and the county of Hertfordshire.

A colleague writes of him: "Dr. Harford's unexpected death will be a blow to many besides his intimate friends. The work which he did as honorary secretary of the Ophthalmic Benefit Committee was undertaken for the good not only of his profession, but, as he firmly believed, for that of the public. During the last six months he had become known to many of his fellow ophthalmic surgeons in this connexion, and it is pathetic that he should be taken just at this moment when his efforts appear likely to bear fruit."

Dr. Harford was an enthusiastic advocate of temperance, and for many years was honorary secretary of the Native Races and Liquor Traffic United Committee, and in 1910 was secretary to the Church of England Temperance Society. He also filled the office of joint secretary in the Society of Tropical Medicine and Hygiene. He is survived by his widow and one daughter.

NAVAL MEDICAL COMPASSIONATE FUND.—At the quarterly meeting of the directors of this Fund, held at 68, Victoria-street, London, S.W., on July 7th, Surgeon Vice-Admiral Joseph Chambers, Medical Director-General of the Navy, in the chair, the sum of £65 was distributed among the several applicants.

INTERNATIONAL CONGRESS OF RADIOLOGY.

THE first International Congress of Radiology was held on June 30th and July 1st, 2nd, 3rd, and 4th, at the Central Hall, Westminster, under the presidency of Dr. C. Thurstan Holland.

The Congress was attended by about 350 delegates, hailing from the Argentine, Belgium, Canada, Czecho-Slovakia, Denmark, France, Germany, Hungary, Holland, Iceland, the Irish Free State, Italy, Norway, Poland, Russia, Sweden, Switzerland, and the United States.

FORMAL OPENING BY H.R.H. THE DUKE OF CONNAUGHT.

H.R.H. the Duke of Connaught opened the proceedings and extended a welcome to the foreign delegates in the large hall. Prior to his speech, representatives from each country were introduced to him. The Duke reminded his hearers that it was now 30 years since Rontgen discovered X rays, and said it was a great tribute to the value of this discovery that in 1925 such a large body of medical men and scientists should have met to discuss further developments of it. The use of the rays to detect faults in steel was now an established procedure, and their application to coal was also making progress. In diagnostic and curative ways, too, the rays had given relief to countless thousands, but further research was needed before the value of the rays in the treatment of disease could be accurately assessed. The consuming question in the minds of medical men and scientists was the cause and treatment of cancer, and such meetings as this for the interchange of ideas and experiences could only be for the common good, besides their mission in fostering cordial international relationships. Not all smaller hospitals were able to have an X ray equipment, and he expressed admiration of the effort being made by the British Red Cross Society to provide the services of mobile X ray units, which could be taken to the bedside of patients. His Royal Highness also referred to the recently formed British Institute of Radiology, the aims of which were to promote friendly relations and the exchange of ideas with other radiological centres throughout the world, to look after the interests of all who were associated with radiology, and to organise teaching and research. In France very valuable work was being carried on, largely by the aid of Government grants for the purchase of large quantities of radium, and Belgium was very energetically prosecuting research into the properties and possibilities of these agents; while in Germany there had been established a definite technique for particular diseases. In this city, he said, we had the Radium Institute, which was employing a large quantity of radium; and the Government had placed at the disposal of the Medical Research Council a large quantity of the salt, which was distributed to a number of hospitals and research centres. The British Empire Cancer Campaign had also been interested in radium and X ray research, and had granted considerable sums of money for approved schemes of research and the supply of radium to centres. In addition the Ministry of Health was conducting inquiry into the results of the treatment of cancer, and it was hoped that as a consequence of this large quantities would be placed at the service of the medical profession. In declaring the Congress open, His Royal Highness said he prayed that every success would attend its labours.

Welcome by the Minister of Health.

The Right Hon. Neville Chamberlain, M.P. (Minister of Health), followed with a speech of welcome on behalf of the Government. He said it was not very surprising that this should have been the first international congress on the subject, seeing that radiology was still in its infancy. When Rontgen made his discovery 30 years ago, only those in close touch with scientific questions could have anticipated what that discovery would yield for the service and benefit of mankind. Very considerable progress had been made of recent years in regard to the application of X rays, radium, and sunlight in the diagnosis and treatment of disease; but each new discovery only seemed to raise the curtain a little higher and to reveal the possibility of even further discoveries. He did not believe that real advance could be made except by the interplay of minds which were continually being devoted to these problems. It was the duty and the policy of this country to do all it could to stimulate and encourage research. At the present time radium was both scarce and dear, and until someone showed how it could be made out of house refuse, or beetroot, he supposed there would always be a difficulty in securing a sufficient quantity of the precious substance.

The path of exploration, Mr. Chamberlain said, had always been strewn with wreckage, and often the explorers in the field of radiology had been no exception in that respect. Earlier in the inquiry regarding these substances and sources of power men had fallen victims to dangers which at the time were unsuspected. All honour to those martyrs who had so suffered, some of whom had lost their lives in the work. It was, however, a comfort to those who suffered in the acquisition of knowledge to feel that they had at any rate buoyed the rocks for others, and through them had prevented suffering by many thousands of fellow creatures. He believed that by the holding of such congresses further triumphs for the benefit of humanity would accrue.

Sir Humphry Rolleston expressed the thanks of the Congress to the Duke for his kindness in performing the opening ceremony, and referred to the close association of this Congress with the British Institute of Radiology, which carried on work in this sphere steadily from day to day. The Institute deserved all possible encouragement, as it was a kind of central bureau where all matters concerned with radiology could be stored, discussed, and provided for the use of any medical man desiring it. It was also a centre of instruction for the men who were taking up radiology as their life-work, as a preliminary to taking their diploma. In addition it was to be the home of the Mackenzie Davidson Library, and the site of a museum in memory of the late Sir Archibald Reid, who had done so much for radiology, particularly during the war, and was a moving spirit in the foundation of the Institute. The Institute would also be a meeting place for colleagues from foreign countries, the Dominions, and the Colonies.

The work of the Congress was carried out in three separate sections—Physics, Electrotherapy and Actinotherapy, and Radiology, of which the respective chairmen were Mr. C. E. S. Phillips, Sir Henry Gauvain, and Dr. A. E. Barclay.

INTERNATIONAL UNITS AND STANDARDS FOR X RAY WORK.

This important question was discussed very fully by a combined meeting of the Sections of Physics and Radiology.

Sir William Bragg, F.R.S., in opening the subject, said that in order that a science might progress it had always been necessary to render comparison of results easy. Lord Kelvin had well said that nothing really progressed until it had been put into terms of arithmetic. The subject of X ray standards was beset with real difficulties, perhaps more so than the choice of any other unit which science had had to devise. One of the greatest difficulties was that due to the difference between quantity and quality, the difference between the amount of energy and the wave-length which carried it. Nor was the subject simplified by the occurrence of scattering of the rays and the consequent formation of new beams. These difficulties made it all the more desirable that the workers in all countries should meet and arrive at an understanding as to the best method of comparing the results arrived at. Various countries had already been working at the problem, and he was a member of a standing committee appointed by the Rontgen Society and the Physical Society to study the question. To arrive at such an understanding no undue stress must be laid on any one part, for a standard must be largely a matter of compromise. Three grades could be set out: (1) The determination of a scientific unit; (2) a description of a standard apparatus for making comparisons; (3) a comparison of the results of treatment. The last of these was entirely a hospital matter. There seemed no reason why these three problems should not be attacked together.

Dr. Béclère (Paris) said the erythema dose was a biological unit, and took the place of all the physical units previously employed. But the sensitivity of the skin varied within quite wide limits. This, however, would not be so important in regard to dosage if all radiotherapists had adopted the same average value—i.e., the same "h. e. d." This was found to vary not only in the same university, but also in the same clinic according to the apparatus concerned. He regarded the skin erythema dose as an unfortunate standard; there should be a physical unit, common to all countries. A feature of weakness in the ionometric method was the difference in the various electrometers. The German Rontgen Society adopted a unit which was based on the electrostatic unit, as well as that chosen by Villar. The chief need at the moment was that radiologists in the different countries of the world should admit the necessity of standardisation of dosage, and proceed to elect an international committee to study the question and submit such a working standard, to embrace not only the quantity to be given, but also the quality of the rays.

An International Quantitometric Unit.

Dr. I. Solomon read a paper on this subject, in which he said the ionometric was the best method of measuring X rays. It was necessary to express the quantity of X rays in terms of a dosimetric notation of an objective character. The choice of a quantitometric unit instead of the electrostatic unit, with the definite conditions proposed by Behnken and adopted by the German Radiological Society, was in fact very satisfactory; but Behnken had shown that differences in technique would prevent its generalisation.

Dr. Behnken stated, in German, what were the points of value in his suggestion. A paper was also read which had been sent by Prof. H. Martius and Dr. Grebe, of Bonn, on the dosage of X rays in absolute units, and the quantity of radiation necessary for the production of skin erythema. Experiments with a Behnken chamber on one side, and one with air at atmospheric pressure on the other, and the difference in these two conditions was found to be very slight. Neither was there much difference when chambers of 10 and 25 cm. diameter were used. The difference between the values for the production of skin erythema, however, was one which needed to be cleared up.

Dr. Altschul (Prague) said a dosimetre was required which would indicate the dosage at each moment of the irradiation, and he described an instrument which would measure the work of a beam of rays.

Dr. N. S. Finzi seconded the resolution, calling for a standard unit of X ray dosage. The proposed committee, he said, would have to determine first a physical unit, then, if possible, a biological unit. The first of these could readily be settled if questions of priority and country of origin were left out. It was not the first unit which was required for adoption but the best. The question of a biological unit was a far more difficult one, because of the number of factors which must necessarily come in. The biological unit would probably vary with the wave-length of the radiation employed, and with the time during which it was applied. For example, if one gave half units on two successive days, the result would not be the same as that from one unit given on one day. If radium should be used as the standard, he suggested that all the beta radiations should be got rid of by a strong electromagnet. In some of the measurements which had been made the beta rays as well as the gamma were used. He also suggested that the committee might consider whether the question of kilovolts of the supply—i.e., the wave-length—should be taken into consideration in determining the unit.

The Chairman (Mr. E. S. Phillips) strongly supported the idea of an international committee to set up a standard unit of X ray dosage, and asked for a vote on the abstract principle. This was unanimously favourable.

Prof. Sidney Russ (Middlesex Hospital) said that now the need for a physical standard in X ray work had been established he did not think much delay would ensue in bringing it about. But one or two considerations needed to be cleared up before finality could be expected. Comparison of the general resolutions of the English physicists with those emanating from Germany showed some differences of opinion as to what was most urgently required. It seemed to be generally agreed that what should be measured was the ionisation in air, apart from any secondary phenomena which might take place in the walls of the vessel, or any electrode effect, or any other effect than that produced in the process of ionisation of the air. But if a beam of X rays was allowed to enter this air space and a certain ionisation resulted, it was difficult to know what was going to happen when a totally different beam entered that space. If those two beams gave the same ionisation it must not be concluded that they were of the same intensity. It was necessary to decide definitely upon some wave-length as that to which further intensive measurements must be referred. A very interesting question was that as to what was the best wave-length to take before making use of a general expression.

Prof. Wintz (Erlangen) said an international standard of dosage was necessary not only for exact work, but also for settling scientific controversies. It was better to take a definite and definable physical unit than an arbitrary quantity of radium as the standard. International agreement was necessary on two points: (*a*) the fixing of a physical standard unit for measuring primary radiation, (*b*) laying down principles of measurement for the biological dose. In his own clinic a standard had been in use based upon radium.

Dr. E. A. Owen (National Physical Laboratory) said that since the publication of the first results showing the depth and distribution of Rontgen rays in the human body more experiments had been carried out, and determinations made by the photographic method, as well as by ionisation. There was found to be less scattering of rays around the field in deep doses than for more superficial ones, and the character of the curve in the two was different.

Dr. Glasser (America) said that in his laboratory a large chamber had been used for measurement, and the unit had been measured and practically applied.

Prof. Friedrich (Freiburg) said attempts to measure the X ray energy absorbed within human tissue had not been a success; it was necessary to strive after an absolute physical unit.

Dr. Holfelder (Frankfurt) said he felt suspicious regarding the adoption of any one single ionisation measurement, on account of the number of errors which crept into ionisation measurement. Several must be taken at different times. There was no guarantee of uniformity of the rays used at different places.

Prof. Holthusen (Hamburg) said that in checking two instruments with gamma rays it was not certain that the same results would accrue as with X rays. And it was necessary to distinguish between the unit and the biological effect of a given wave-length.

Prof. Crowther remarked that if the energy of the rays and the wave-length could be measured, the radiation would be known absolutely, both as regards intensity and quality. He hoped to see the unit fixed in terms of radium, and for the reason that the gamma rays of the latter were so penetrating that the ionisation chamber could never be efficiently shielded from them. He trusted that the proposed international committee would adopt something on the lines of the electrostatic unit, as that was quite definite.

Dr. E. C. Ernst declared that the radiologists in America would be only too happy to help forward this work.

A group to work on this matter was decided upon, with Sir William Bragg as chairman.

PROTECTION OF THE WORKER.

Dr. G. W. C. Kaye (National Physical Laboratory, London) opened a discussion on *Protective and Manipulative Methods in Relation to X Rays and Radium* in the Section of Physics. He referred to the birth of a committee for coöperative action emanating from the Royal Society of Medicine and the Rontgen Society, and said the recommendations made by this committee had been widely adopted, and it resulted in a general raising of the standard. One most important result probably was to end the deplorable list of X ray martyrs, and the active support of the Home Office, the Ministry of Pensions, and Ministry of Health had resulted in the extension of the scope of the Workmen's Compensation Act to include lesions caused by exposure to the rays. In a very busy department protection should be much more elaborate than in a department which used the rays only occasionally. In some of their activities the X ray workers could not be completely shielded from irradiation, as some degree of scattered radiation was unavoidable. Various persons showed a different degree of sensibility to the rays, and indeed the same individual differed in his immunity from time to time. Foolhardiness could never be left entirely out of account in dealing with human beings, but the radiologist, realising the danger of dermatitis, possibly cancer, was not likely to tempt Providence in this matter. He did not, however, always appreciate the result of scattered radiation. Rays were given off from the body of a person who was subjected to X rays, and the scattering produced by the air in the room in the vicinity of the X ray tube was something like that of the primary radiation beam. The primary precaution was to surround the X ray bulb with adequate protective material except, just at the appropriate aperture, and in diagnostic work screening was necessary for the protection of the operator. If the scattering was excessive, the operator should be behind a screen or wall, and this scattering rendered inadvisable the use of the cubicle system. Each outfit should be protected by walls extending from floor to ceiling, the floor and ceiling themselves also being protected. The target of the tubes should not be pointed towards the controls. The protecting lead for a strength not exceeding 70,000 volts should be at least 1½ mm. thick, and for 100,000 volts 2 mm. thick, 3 mm. for anything beyond. Usually the manufacturer had risen to the occasion; it was all a matter of design. Dr. Kaye said there was a danger in using gamma rays to test the protection of materials, as these made the protection appear much better than the actual. Always wherever possible the bulb should be surrounded by protective material, and if the latter were lead, it must be adequate for the prevention of sparking. All protective boxes should be tested for leakage. He was surprised that the open bulb was still being used, as in many cases it afforded no protection at all, and where it was employed it was often possible to take a radiogram of the hand in any part of the room. He emphasised the need of providing ventilation of enclosed spaces used in X ray work. Where weight of protective material was a consideration, it was important to remember that lead was the lightest of the protective substances commonly employed. For fluorescent screens not less than 2 mm. of lead was indicated, or 1 mm. for portable screens.

Generous ventilation of the X ray rooms was of an importance only secondary to that of actual physical protection; failing this, workers suffered from depression, headache, nausea. Sometimes it was difficult to persuade even hospital authorities as to the necessity of this open ventilation. He also thought that by means of bright paint on the walls these rooms should be made as cheerful of aspect as possible. The floor space for the radiologist should be adequate, and should be of wood, cork, or rubber. The ceilings should be not less than 11 feet high, and the conductors at least 9 feet from the floor. Efficient earthing of all the metal parts was also important, and the main switches should be readily accessible, and there should be no possibility of their being accidentally cut off. Seven hours was a reasonable day for X ray workers, with Sundays and two half-days weekly off duty, and a month annual holiday. He proposed that steps be taken to secure X ray unification.

Dr. E. A. Owen said that barium plaster showed an absorption of the radiation which varied greatly with the thickness of the material; he illustrated by graphs that with an increased thickness the character of the curve altered. It was now necessary to use very large protective boxes for ships, so that in some cases they had to be moved about by means of tackle. In the Phillips tube the protective device formed part of the bulb itself, which was the ideal principle.

Mr. Hector Pilon (Paris) read a paper on Protection in Radiotherapy, in which he reminded the meeting that the X ray bulb radiated in all directions, and therefore enclosure in a box was necessary. But all the boxes were of large size. He illustrated and explained an oil-immersed tube, of the same size as the Coolidge universal tube, and which could withstand 200,000 volts on the direct current. Every part of the glass wall was cooled and had the same temperature, thus the life of the tube was lengthened as no part of it had a larger share of work than did other parts. If the box was earthed, the patient ran no risks of receiving an electric shock. Another device was shown by which the tubes could be placed in a lead cylinder, in which they were easily adjustable in any position. The oil itself was an insulating substance.

Dr. V. E. Pullin (London), who was, he said, looking after the question of protection from X rays in 15 service hospitals, also laid great stress on the need for efficient ventilation. Possibly the feelings of depression and the headaches were due to a physiological effect related to the ionisation of the atmosphere. Forced and efficient ventilation he placed second only to primary protection. He related an incident in which several patients in a ward above an X ray room had ulcers on the back after leaving the hospital, and these lesions were undoubtedly due to radiation having reached them through the ceiling. In this case the X ray tube was not boxed. He believed an X ray tube could be run in oil if the direct current was used, but it was difficult to do so with the alternating current.

Dr. H. Moore (Sweden) said that even with efficient mechanical protection one often thanked God for the law of inverse squares, as it was clear that the operator should always get as far away from the X ray tube as possible.

Dr. Pullin seconded the proposal of Dr. Kaye that some steps should be taken to secure X ray unification, and it was carried.

The Organisation of a Hospital Radium Service.

Prof. F. L. Hopwood, D.Sc. (St. Bartholomew's Hospital), read a paper on this subject, dividing it into three sections: the efficient use of the available radium; protection of patient, operators, and assistants against injurious radiation; and the safe custody of the radium itself. The radium of which he had charge was distributed among 220 containers, and he showed slides illustrating the holders for radium needles, threading devices, and magnifiers for reading identification marks on the needles, all conceived to avoid handling the radium, and, indeed, making this manipulation easier than handling Protection was afforded by having only a radiologist apply radium and preventing a patient discharging himself with radium on him. He also showed the ingenious drawers, lead-encased, in which the radium was kept. Track was kept of every needle and every piece of radium, and was accounted for at the end of each day He submitted a list of regulations operative in the hospital mentioned, and exhibited specimens of the appliances and boxes used

Mr F H. Glew, who has been handling radium for 20 years, pointed out that notwithstanding all the protective devices against radium emanations there were times when one had to face the enemy in full knowledge that he was the enemy There were moments when the radium would not shake out of the tube, it had become fixed, almost cemented in it and a small drill was needed to get it out. It would be delightful, he said, if radium burned at the time of touching, instead of the burn gradually revealing itself some time afterwards. After his long experience he was an advocate of the operator even looking at the radium at as long a distance away as possible There was great difficulty in removing the active radiation from tubes which had once been charged He deprecated the use of glass tubes in hospitals and busy centres which were ten years old or more, as their critical condition rendered them liable to explode at any time

Dr G Failla (New York) said that in his hospital colour was largely used for the purpose of identifying tubes at a distance. There they had no open wounds to contend with as a result of the manipulation of radium, though the fingers, especially around the nails, became red and scaly

Dr A. E Stein (Wiesbaden) described a medical *carbon arc lamp* in which the carbons were placed in parallel series. The arc light was thus formed between the two carbon points which lay one above the other This position of the carbons enabled the light rays to stream out without any shadowing of the light-crater, which occurred, more or less, in every other form of carbon lamp The Jupiter[1] lamp was fitted with carbons of a special chemical composition The result was that these lamps produce numerous ultra violet rays down to 217, as well as notable proportion of infra red and heat rays. The spectral values of the light produced by the arc, he held, approached more nearly that of the natural solar rays than those from any other lamp made

On Thursday afternoon a large party from the Physics Section paid a visit of inspection to the National Physical Laboratory at Teddington

RADIUM AND X RAY THERAPY

Dr S A. Heyerdahl (Oslo) contributed a paper on the use of radium for *actinomycosis* In his first case there had been two operations without permanent result, and radium was then tried, and for ten years (to the present date) there had been no relapse His usual procedure now was to give two or three applications of radium, with a six weeks interval The good results lasted for two to ten years

Dr F Tománek, of Prague, who represented the Czech Society of Radiology, related his experiences in treating *pernicious anæmia* with radium, and said that by massive irradiation of the spleen over long periods patients with this condition had been sustained for a long time, even when other treatments, such as blood transfusion, had failed Radium treatment seemed preferable to splenectomy for this disease. He also read a paper giving his results of prolonged irradiation for *leukæmia*. He used from 80 to 100 mg of radium over the whole spleen, taking it in 25 sections, giving 80 per cent. of the erythema dose There was a reduction in the number of leucocytes, the blood picture improved, and at the end of a year no relapse had occurred

Dr R H Stevens (Detroit, U S.A) gave an account of his treatment of four cases of *leukæmia* with intravenous injections of radium during the past year Three had not been successful, as two of the patients had died, but in the fourth 200 mg was injected last October with marked improvement and a further dose in January, after which the leucocyte count was normal

Cancer of the Breast

Prof Wintz (Erlangen) read a paper on the Irradiation of Breast Cancer He said that the position of X ray therapy in regard to the treatment of cancer of the breast was still very much disputed He had now at his disposal the results of fully 300 cases of cancer of the breast, which he had treated by the same method between 1918 and 1924 He urged all experienced X ray specialists to publish their statistics, and asked those who had had experience of a few cases only to send their results to him to be incorporated in the collected statistics which he was about to compile He advised those compiling statistics to adopt Steinthal's classification Group I.: Where the tumour was restricted to the breast and can be moved, no infection of axillary or supraclavicular glands. Group II Where the tumour had already infiltrated the surrounding region, axillary glands palpable Group III Where the glands in the supraclavicular region were palpable and, in some cases, metastases were also apparent. For the final result cases were arranged in two groups (1) Lost cases, i e : (a) All those who had died whether of carcinoma or of an intercurrent disease; (b) those who could not be followed up, and (c) patients who were at the point of death at the end of the three years whether from cachexia or from distant metastases. (2) Clinically cured cases—i.e , those cases in which after careful examination no trace of cancer could be found and whose general condition was sufficiently good to admit of their being regarded as clinical cures. The following statistics were drawn up on this principle —

	Treated	Cured	Lost	Percentage of clinical cures
Group I	21	20	1	95·2
Group II.	41	28	13	68·3
Group III.	44	8	36	18·1

An observation time of three years, he held, was sufficient, especially when those cases who had died from intercurrent diseases were included At the same time it was advisable to publish observations extending over longer periods since, in the case of carcinoma, it was correct to speak of a cure only after five years had elapsed For the purpose of comparison he gave first of all the figures for Groups I. and II for the three-year observation period

	Steinthal	Treated	Cured	Percentage
Three years after treatment	I and II.	62	48	77·0
„	III.	44	8	18·1
Four years	I and II	47	31	65·9
„	III	36	3	8·5
Five years	I. and II	35	17	48·6
„ „	III	11	2	18·8
Six years „	I and II.	23	9	39·1
„	III.	10	1	10·0
Seven years „	I. and II	15	3	20·0
	III	4	—	—

The statistics were similar to those of uterine carcinoma He said that the results shown by his statistics under Group II. were better than the average results shown by the surgical statistics. Group I offered ideal competition between the surgical and X ray treatment. If satisfactory results were to be obtained three years after the conclusion of treatment, X ray treatment of the tumour alone was not sufficient. It was essential (a) to apply the requisite dose for the destruction of the carcinoma cells to the axillary and supraclavicular regions as well; (b) to give a carefully planned scheme of after-treatment; and (c) to take special care when irradiating carcinoma of the breast to prevent lung fibrosis

---

[1] Agent The Holborn Surgical Instrument Company, Ltd

Dr. Casman (Antwerp) gave a cinematograph demonstration of the actual burying of radium tubes in the breast in a case of cancer. In cancer in this region he preferred to employ the three processes of X rays, radium, and surgery. From the aspect of pure surgery there were two difficulties—the unsuspected extent of the disease, and the impossibility of surgically removing the whole of it. And it was not always possible to ensure that the needed amount of X ray energy was being absorbed by the new growth. The field for the employment of radium was a more limited one, but the action of this salt was more powerful than X rays. In a given case he began by applying X rays to the whole diseased area. Four or five weeks later he made a small incision and carefully buried radium tubes surrounded by gauze and fixed at a certain distance from the limits of the area dealt with.

Dr. B. J. Lee (New York) reported to the meeting eight cases of primary operable carcinoma of the breast from the special clinic of the New York Memorial Hospital, all of which had been treated solely by irradiation. At least four and a half years had intervened since the commencement of the treatment. Surgery was not employed in this series either because of the patient's age, or in consequence of her refusal of operation. Dr. Lee was somewhat sceptical as to the end-results in the surgery of this breast disease. The oldest patient in the series, aged 90, was made comfortable for three years by this treatment by means of buried radium. At the end of the three years she died from intercurrent disease. The average age of the series was 58. Nodules could be felt in the axillæ of two of the patients. Three women in the series had X ray treatment only. One of them still remained alive, one died two years, the other four years after the treatment. In two radium alone was used, and radium with X rays in the remaining three. One millicurie per c.cm. of radium was the dosage used, while the X rays were administered from a low-voltage tube, with a six-minute exposure, the focal skin distance being 10 inches and the filtration was through 3–4 mm. of aluminium. Of the eight cases dealt with in the paper, five were now alive and well, two had died from intercurrent disease, and one from metastases. The results, he considered, were very favourable as compared with those achieved by surgery in this disease.

Epithelioma of Tongue Treated by Radium.

Dr. C. Regaud (Director of the Pasteur Laboratory at the Radium Institute, Paris) read a paper on curietherapy of epitheliomata of the tongue and their following adenopathy. Of 174 cases so treated 42 were alive and without any symptoms of cancer at the end of 1924, an apparent cure-rate of 24·1 per cent. In 46·5 per cent. the treatment caused at least the disappearance of the cancer at the local site; in the operable cases alone this figure rose to 63·1 per cent. The paper entered into the therapeutic indications and the leading ideas as to technique. X rays appeared to have yielded bad results in cancer of the tongue. Dr. Regaud expressed his preference for radium puncture by means of platinum needles.

Radium Treatment of Cervical Cancer.

Mr. Malcolm Donaldson (London) gave an analysis of the results he had obtained by radium treatment in 85 cases of inoperable carcinoma of the cervix, as reported when he read his paper at the Royal Society of Medicine. He said he had not yet decided whether it would be better to increase the radium intensity or the period of application. He intended that in his next series the number of needles employed should be increased, while the application time should remain at 144 hours.

Dr. Zweifel, of Munich, said he had used in his hospital a combination of radium and X rays latterly, and among the operable cases there had been 43 per cent. of cures, and 7 per cent. among the inoperable.

Prof. Wintz (Erlangen) expressed the view that squamous-celled cervical carcinoma was much more sensitive to X rays than to radium.

ACTINOTHERAPY.

Sir Henry Gauvain initiated a discussion on actinotherapy. He said the chief point to look to was the clinical result of this form of treatment. He believed that the action of light on the patient was two-fold—on the mind and on the body. The experience at the Alton Hospital was that the light caused an improvement in the mental health. On the body the light had a double effect; first the direct one, including inflammatory response and the formation of pigment; secondly, the remote or indirect effects, which he did not enlarge upon. Pigmentation in this connexion he regarded as important, as patients who pigmented frequently did well in other respects. Light therapy was an intriguing form of treatment because of the unexpectedness of some of its results.

On Saturday, July 4th, the members of the Section of Actinotherapy paid a visit to Lord Mayor Treloar's Cripples' Hospital, at Alton, Hants.

X RAY DIAGNOSIS.

Dr. A. E. Barclay (Manchester) characterised *palpation* under the X ray screen as a complex art, requiring much patient practice, as it depended on a combination of touch and sight. The most important palpation of the stomach was that carried out while the first portions of food were entering it, as it would often reveal a filling defect. Radiographic plates were also necessary, however.

The Radiology of Bones.

Dr. A. Howard Pirie (Montreal) read a paper on *Normal Rarities of Bone Simulating Disease.* He showed on the screen an interesting series of cases, demonstrating ununited patella, simulating fracture, double sesamoid bones in the gastrocnemius, pseudo vesicles on each side of the knee-joint. He had met with five cases of rectus sesamoid, just about the acetabulum, which might be present on one side only. This condition, he considered, must be looked on as a normal abnormality, and appeared to have escaped the notice of anatomists. A separate epiphysis may remain on the second metacarpal bone; this, he held, was a reversion to type, as it was seen in the seal.

Dr. W. H. Stewart (New York) spoke on the time factor in the disappearance of rontgenographic evidence of *Fracture of the Skull.* He said experience had taught us that it was a mistake to be definite about the time required for union of the bones of the skull. In children simple fractures might heal in from six to eight months; in adults the fracture line remained for fully three years. Shelving fractures disappeared more rapidly. Fractures of the occipital bone could be recognised three to five years after the accident. The X ray evidence of comminuted or depressed fractures was usually permanent. He emphasised the medico-legal importance of the time factor.

Dr. A. W. George (Boston) described a method of diagnosing injuries of the atlas and axis by taking an X ray picture antero-posteriorly through the mouth and in the lateral position. Three parallel lines were then drawn passing through bony landmarks on the atlas, axis, and third cervical vertebra, and any divergence of these lines indicated pathological conditions. If, in the antero-posterior position, the patient lying on the table, the space between the atlas and axis were obliterated, that indicated disease of the retropharyngeal structures.

Dr. H. A. Harris (London) gave a demonstration on the screen of the developing centres of ossification of the fœtus from the age of 28 days onwards. He said that out of 100 cases of stillborn infants submitted to an anatomy department there was cervical rib present in 35 (in normal adults the percentage is 0·25).

If cervical rib is present in an adult it has not been acquired, but it means it has not been absorbed. The absorption of the cervical rib is the normal process of development.

Sir Frank Colyer (London) described various pathological conditions of the teeth and jaws. Where the pulp of a tooth died, the periodontal membrane might become infected and a granuloma might form. If this granuloma were surrounded by a layer of dense bone, he did not believe that such a tooth gave rise to systemic infection, but where the dense layer was absent, infection did take place. The presence of this dense layer could be determined radiologically, and the speaker urged that it was in questions such as these that the radiologist could be of the greatest help to the dentist.

X Rays and Pregnancy.

Dr. Carlos Heuser (Buenos Aires) demonstrated on the screen a method of injections of lipiodol into the cavity of the uterus for the diagnosis of early pregnancy, fibroids, and non-patency of the Fallopian tubes. By this method it was possible to determine the existence of pregnancy in the first or second month. Injections had been given in 48 cases, and in none had abortion occurred.

Dr. Lars Edling (Lund, Sweden) said that with the X rays he was able in about 200 cases to diagnose pregnancy at the end of the third month or the beginning of the fourth, but not earlier. He had never used lipiodol.

Prof. De Nobele (Ghent) read a paper on the action of Rontgen rays on the evolution of pregnancy and the development of the fœtus. His conclusions were that the erythema X ray dose had an indisputable effect on the evolution of pregnancy in the guinea-pig and the rat; in the majority of cases the embryo died, and the earlier the rays were applied the more certain was that result. If the embryo was not actually killed, it developed into a monster. He found also that irradiation in the guinea-pig produced a tendency to formation of ovarian cysts.

Dr. E. H. P. Cave (Harrow) described his method of examining radiologically the male urethra and the bladder, using lipiodol.

Cholecystography.

Dr. R. D. Carman (Mayo Clinic, Rochester, Minn.) and Dr. Sherwood Moore (St. Louis) each read a paper on the development of this branch of diagnostic radiology, and described Graham's method of the use of sodium-tetrabromphenolphthalein and sodium-tetraiodophenolphthalein. Dr. Carman's paper appears at some length elsewhere in this issue. Dr. Moore said that what was now wanted was more information about the physiology of the gall-bladder, and this was being rapidly worked out.

Dr. G. T. Haenisch (Hamburg) recommended the direct duodenal method, by means of a sound, of giving the dye for diagnostic purposes. In this way unpleasant symptoms were avoided.

Dr. Stewart (New York) said he preferred to put the tube into the jejunum, as thus there was no vomiting.

Dr. R. E. Roberts (Liverpool) said that he used the bromine salts intravenously, and no accidents had occurred when attention was concentrated on slow injection.

Dr. J. T. Case (Battle Creek, Michigan) said that the dye showed up inflammatory processes outside the gall-bladder. At Battle Creek tetra-iodol was used intravenously as a routine method in cases where the dye, given orally, did not enter the gall-bladder.

Dr. Moore, in replying, said that oral administration of the dye should be the routine method, and when the diagnostic result was doubtful the intravenous method should then be adopted.

Studies on the Alimentary Tract.

Dr. De Backer (Ghent) read a paper on the *alimentary canal in the normal infant.* In the discussion which followed, Dr. L. T. Le Wald (New York) said that any case of vomiting in a baby should be examined by X rays for the existence of hypertrophic pyloric stenosis. He considered that the colon in children needed more elucidation. It was held by some that the pelvic colon was unusually long in the first few years of life, and that this was subsequently outgrown; in the speaker's opinion, however, a long colon, if present in infancy, persisted throughout life.—Prof. Gosta Forssell (Stockholm) said that a contraction of the pyloric end of the stomach was often mistaken for contraction of the pylorus. Hypertrophic pylorus might also be present.

Prof. Forssell read a paper on some further observations on the *Motor Mechanism of the Mucous Membrane of the Digestive Tract.* By means of many excellent radiograms and photographs of fistulæ of the small intestine in man, he showed that the folds of the mucous membrane did not depend passively on contractions of the muscular wall of the gut. Other forces came into play, and attention was drawn to the muscularis mucosa. Already in 1913 Prof. Forssell had said that the muscularis mucosa was the independent factor in producing movements of the mucous membrane of the alimentary canal, and this contention had since been more fully demonstrated. The most convincing proof had been from histological studies, when it was shown by a number of observers that the overlapping of muscular cells in the muscularis mucosa occurred in the folds of the mucous membrane this was most distinct in the stomach cavity.

Dr. A. Frankel (Berlin) gave a demonstration of a new symptom of *gastric ulcer*—which he called the cross-bar symptom—within the folds of the membrane by means of Rontgen therapy, and Dr. N. Ratkoczi (Budapest) showed on the screen several cases of duodenal ulcer and adhesions of the duodenum.

Dr. H. H. Berg (Frankfort-on-Main) read a paper on the direct signs of duodenal ulcer, and showed on the screen the effects of various drugs on the motility of the gall-bladder, illustrated by the case of a patient who had a large number of gall-stones in the bladder.

In speaking of intermittent obstruction of the small intestines, Dr. H. M. Imboden (New York) said that if the duodenum were filled and could not empty itself, a hand pressed on the abdomen while the patient took a deep breath would bring about emptying.

Dr. M. I. Lifshitz (Karkow) presented Dr. Lemberg's paper on the rontgenological diagnosis of *chronic appendicitis* based on a study of 105 cases at the Ukranian Radiological Institute, Karkow.

Dr. R. Feissly (Lausanne) discussed the diagnosis of *ileocæcal tuberculosis* in relation to operation findings.

Dr. J. T. Case (Battle Creek, U.S.A.) showed skiagrams of 70 cases of *diverticula of the small intestine.* When diverticula were multiple, the larger ones were nearer the stomach, the smaller ones more remote from it. X rays had enabled him to distinguish false diverticula from true. Three out of four of the 70 patients had no symptoms referable to the diverticula.

Dr. Jacques Forestier (Aix-les-Bains) read a paper on radiodiagnosis by means of lipiodol of *tumours and other causes of compression in the spinal cord.* He emphasised two points (1) that the radiograph must not be taken in the lying position, and (2) that lipiodol must not be injected earlier than the tenth day after the first lumbar puncture had been performed. He also described the injection of the seminal vesicles with lipiodol.

Two most interesting items of the programme were the cinematographic films exhibited by Dr. Lewis Gregory Cole (New York), the one illustrating most graphically the mechanism of the stomach, and the other the spread of tuberculosis in the lungs.

During the Congress an exhibition of radiological studies was on view at the house of the British Institute of Radiology, 32, Welbeck-street, and in the basement of the Central Hall, Westminster, the following firms had assembled a remarkably fine collection of radiological apparatus and matter relating to that specialty:—

Acme International X-Ray Co., Chicago; Aimer, G. C., London; Andrews, Cuthbert, London; Dean, A. E. and

Co., London ;' Denver Chemical Manufacturing Co., London ; Gaiffe Gallot et Pilon, Paris ; General Radiological and Surgical Apparatus Co., Ltd., London ; Hanovia Quartz Lamp Co., Ltd., British, Slough ; Holborn Surgical Instrument Co., Ltd., London ; Kahlbaum Chemische Fabrik, Berlin ; Kodak Limited, London ; Muller, Hamburg ; Newton and Wright, Ltd., London ; Patterson Screen Company, U.S.A. ; Philips Lamps Ltd., London ; Radiguet and Massiot, Paris ; Radium Belge, Brussels ; Rothband, W. S. and Co., Manchester ; "Sanitas," Electricitätsgesellschaft, Berlin ; Schall and Son, Ltd., London ; Seeman, Dr. H., Freiburg i. Br. ; Solus Electrical Co., London ; Victor X-Ray Corporation, U.S.A. ; Watson and Sons, Ltd., London ; X-Rays Limited, London ; Zimmerman and Co. (Chemical), London ; Zimmerman and Co. (Photographic), London.

LECTURES.

Two formal lectures were delivered during the Congress, the first being the Silvanus Thompson Memorial Lecture, given on the evening of Wednesday, July 1st, by the Duc de Broglie, of Paris. He took as his subject the absorption of x and y radiations and the secondary radiations which accompany them. On Friday, July 3rd, Sir Berkeley Moynihan, of Leeds, as Mackenzie Davidson Memorial Lecturer, spoke on the *relationship of radiology and surgery.* He said that the radiologist had now given certainty to the surgeon's diagnosis—in kidney and gastric diseases errors of diagnosis had proved extremely lamentable until radiology put things right. No words could be too strong, he added, to denounce the action of the surgeon who operated on a stomach case merely because someone—not the radiologist—had made a diagnosis of gastric ulcer which an inspection of the stomach did not confirm. If a case were wrongly diagnosed and medical treatment alone given, then little harm was done—physicians and surgeons might both be at fault, but the fault of the surgeon was far graver. Why could they not arrange, he asked, that no diagnosis of gastric ulcer should be the warrant for medical or surgical treatment until that diagnosis was made by the radiologist or by the surgeon on the operating table? Radiology had also helped to explain why so many diseases mimicked the condition of gastric ulcer. By clinical means, he said, it was not possible to detect gastric carcinoma in the curable stage of the disease, but, given time, the radiologist could diagnose the condition at that stage. The gifts of radiology to medicine and surgery, he concluded, were things for which humanity at large could be profoundly thankful.

SOCIAL FUNCTIONS.

The Congress dinner was held in the Hotel Great Central, N.W., on July 2nd, the President, Dr. Thurstan Holland, in the chair. The company numbered over 400, many lady guests of members being present. The President, in expressing his gratification that the Congress was to be the first International Congress of Radiology, paid a tribute to the work of two pioneers who had recently died, Sir Archibald Reid and Prof. F. Bérgonié, of Bordeaux. The driving force behind this Congress, he said, had been Dr. Robert Knox, chairman of the organising committee, ably assisted in the entertainment of the lady visitors by Mrs. Knox and the ladies' committee. The delegates of the various countries represented then spoke in succession, the order of precedence being alphabetical. There spoke for the Argentine, Dr. C. Heuser ; Austria, Prof. A. Schuller ; Belgium, Prof. De Nobele ; Canada, Dr. Howard Pirie ; Denmark, Dr. C. O. Sonne ; France, Dr. A. Béclère ; Germany, Prof. A. Dietlin ; Holland, Dr. Heilbron ; Hungary, Dr. N. Ratkoczi ; Irish Free State, Mr. M. R. J. Hayes ; Italy, Prof. M. Ponzio ; Norway, Dr. S. A. Heyerdahl ; Poland, Count Debecki ; Russia, Prof. M. Nemenow ; Czecho-Slovakia, Dr. W. Altschul ; Sweden, Prof. G. Forssell ; Switzerland, Dr. R. Feissly ; and the United States of America, Dr. P. M. Hickey. The dinner was marked by pleasant cordiality, both international and individual, and concluded with a dance.

The League of Nations Union entertained the delegates to luncheon at the Hotel Cecil, Strand, on Friday, July 3rd, Lord Cecil of Chelwood in the chair. He said that the science of radiology owed much to international thought and action, and as the conference in London was an example of internationalism in science, the League of Nations Union was delighted to extend to the delegates the warmest welcome. Dr. John Muir, assistant secretary of the Congress, replied.

On Saturday afternoon, July 4th, at the conclusion of the Congress, a garden party was held at Imber Grove, Esher, by invitation of Dr. E. R. Morton, the chairman of the hospitality committee.

THE INTERNATIONAL COMMITTEE

At the final meeting of the delegates on July 4th an international committee was formally constituted, with Prof. Gorsta Forssell of Stockholm, Sweden, as chairman ; Dr. C. Thurstan Holland, of Liverpool, as vice-chairman ; and Dr. Stanley Melville, 9, Chandos-street, London, W. 1, as secretary. It was decided to hold the next international conference at Stockholm in 1928.

Correspondence.

"Audi alteram partem."

DISABLEMENT FROM CHRONIC RHEUMATISM:

THE NEED FOR A CONCERTED EFFORT.

To the Editor of THE LANCET.

SIR,—Official returns in two countries [1] have recently set forth the prevalence of disablement from rheumatic diseases. In Sweden, as no doubt elsewhere, *senility* and *cardiovascular degeneration* account for more than half the cases of permanent pensionable invalidity. Apart from these "incurable" causes, *articular rheumatism* comes first among the list of disabling maladies, accounting for 9·1 per cent. of the Swedish cases, as against 5·8 per cent. accounted for by pulmonary tuberculosis. The British Ministry of Health, in their classification of "rheumatic diseases," include almost equal numbers of articular and non-articular cases, such as lumbago. Adopting this wider use of the term, rheumatism causes (as we now know) nearly one-sixth of the total industrial disability in England, with an estimated expenditure of £2,000,000 for sick benefit and a loss of 3,000,000 weeks of work per annum. If non-articular cases were included in Sweden, the proportion would probably be much the same (one-fifth to one-sixth of the grand total).

Dr. Kahlmeter makes it clear that rheumatism and tuberculosis are by far the most important causes of disablement (from disease), and that rheumatism imposes a heavier economic burden than appears from the statistics, because the invalidity caused thereby is of long duration, entailing not only a great deal of mental and physical suffering, but a heavy expense to the community. He also points out that the other main disabling diseases are relatively well cared for, but that rheumatism receives little assistance. In Holland and Germany also, we understand that the disablement of workers from this cause is an equally serious problem. Dr. Kahlmeter may well ask whether the State cannot do something to mitigate the disability of such large numbers of workers.

It has been pointed out in the report of the Ministry of Health that treatment of chronic rheumatism is entering upon a more hopeful phase. It is all to the good that the dangers of chronic focal sepsis are now better recognised and provided against, but in our opinion this is only half the battle. In all likelihood there are ætiological factors apart from sepsis, as is evidenced in osteomalacia, which is probably a deficiency disease, by changes in the spine indistinguishable from spondylitis deformans. Chill, traumatism, tubercle, and endocrine disturbance are other probable factors in causation. The investigation of possible metabolic abnormalities is urgently required, and should be one of the chief functions of any clinic established to deal with chronic rheumatic diseases. At the same time the effects of physical remedies—heat and cold, radiant and electrical energy and movement, and the internal use of waters—should be studied and their efficacy compared. In the present state of our knowledge we can but advocate measures directed to improve the general health, to prevent the development of rheumatic tendencies, to increase the resistance of the body to infection, and to promote the absorption of exudations and deposits.

---

[1] The Incidence of Rheumatic Diseases. Ministry of Health Reports, No. 23. London. 1924. Examen statistique des causes d'invalidité, fait d'après les demandes adressées à la "Direction des Pensions de Retraite" pendant l'année 1918, sur lesquelles les pensions supplémentaires furent accordées. Par G. Kahlmeter, Docteur en médecine, Médecin consultant de la "Direction des Pensions de Retraite," Stockholm. Acta Medica Scandinavica, vol. lix., Fasc. i.–vi.

A Committee on Rheumatism has now been appointed by the International Society of Medical Hydrology. It will take these official reports as the basis of its inquiries, which will have for their object some concerted action in the campaign against rheumatic disability in the countries most affected thereby. Practitioners at the health resorts with experience in the treatment of rheumatic diseases, who are disposed to assist the work of the Committee, are requested to communicate with Dr. Ray at 6, Bentinck-street, W. 1.

May we quote two examples of the treatment of chronic rheumatism, carried on for a long period of years, in order to indicate what might be done, with an ampler organisation and equipment?

(1) A charity was founded at Buxton more than 300 years ago for the treatment of the poor suffering from rheumatic disorders. It is unnecessary to quote the figures, but the Devonshire Hospital now accommodates large numbers of industrial workers, recommended by the approved societies, from all parts of the country, many of the more serious cases returning from year to year. It may be added that many observers have recorded strong reactions in rheumatic patients submitted to the Buxton waters. We have here, for many generations, a customary treatment of chronic rheumatism, presenting now a large field for the differentiation of cases and for the scientific use of certain physical methods.

(2) In Holland, where there are no spas, a clinic for physical treatment was opened at Amsterdam in 1905. Since that date about 10,000 rheumatic cases have been treated by baths, manipulation, and electricity. Articular and non-articular cases were in about equal numbers, with many mixed cases. One of us (J. v. B.) has had under his own care during the last 15 years nearly 5000 cases of chronic arthritis, many of which, after temporary improvement, return year by year. The following conclusions are drawn from the work of this clinic: (a) A sedentary life in cold, damp localities plays a great rôle in the development of chronic rheumatic affections. (b) Persons of an arthritic tendency are numerous in Holland, especially among the intellectual classes. When they are exposed to unfavourable external conditions or to accidental toxic invasion, rheumatic developments occur. (c) In these cases the connective tissues become a place of lowered resistance, favourable to inflammatory changes, to parasitic growth, and to atrophy. (d) The influence of mental depression, tuberculosis, and dental sepsis is unquestionable, and that of auto-toxæmia from the bowel probable. (e) Expert treatment at a suitable clinic may, even in unfavourable and progressive cases, maintain the function of the joints, so that invalidity is prevented, whilst treatment by drugs alone is insufficient for this purpose.

We are glad to note that the British Report emphasises the need for further development in the treatment of rheumatism at the spas and elsewhere. Certain natural waters and baths are of proved efficacy in chronic rheumatism, and, with selected methods of accessory treatment, in our opinion, ought to be made available under proper conditions for the greatest possible number of industrial cases. But the spas can only handle a fraction of the needful cases. Is it not possible to provide clinics for rheumatism in the towns? War-time experience with other forms of disability has shown the great value of clinics, where large numbers of cases can be investigated and treated.

We are, Sir, yours faithfully,
J. VAN BREEMEN.

OUTBREAK OF GONORRHŒA IN A CHILDREN'S HOME.

To the Editor of THE LANCET.

SIR,—On Jan. 26th, 1924, 17 girls between 6 and 10 years old, living in an exceptionally well-administered home, were notified as suffering from gonorrhœal vulvo-vaginitis, confirmed by bacterial examination. Careful inquiry as to the only two admissions in January revealed the fact that one of them (aged 11), admitted on the 11th, was found on the 25th to be suffering from a profuse gonorrhœal discharge. During her mother's absence in service she had been "running wild" and "had intimate relations with men and received money from them."

The home possessed a sufficiency of small slipper-baths, each child had her own towel, and one or more attendants were present during bathing. But as the number of children was large, the possibility of bathing in common could not be excluded, and I formed the definite opinion that the infection was thus spread. Efficient steps were at once taken to prevent further infection, and the management of the outbreak was entrusted to Dr. H. Gluckman, director of the Municipal Venereal Diseases Clinic, whose treatment was on the following lines:—

Bed for ten days; hot sitz-bath twice daily with ʒi. pot. permang. solution (4 per cent.) to each gallon water; then swabbing external genitals with $AgNO_3$ sol. (gr. v. to oz.), followed by hot vaginal douche with pot. permang. sol. (1 in 5000). As improvement resulted, bathing and douching gradually reduced to bi-weekly or weekly douche only. In the more resistant cases, small doses of detoxicated gonorrhœal vaccine were given every fifth day, commencing with 3 minims and gradually working up to 10 minims. In a few cases, complicated by secondary infection, a solution of oxycyanide of mercury (1 in 4000) was used now and again as a vaginal douche instead of the pot. permang.

The effects of treatment were gauged by bacterial examination of vaginal smears. In most cases it was possible to cease treatment in about ten weeks; in a few there was a short temporary relapse. By the end of nine months all were giving a negative result. This has persisted since then, in spite of provocative measures—e.g., silver nitrate instillations, injections of vaccine, and strenuous exercise.

It will thus be seen that most of the sufferers responded readily to treatment, but the eradication of gonorrhœal infection (especially in an institution) is a tedious matter, and nine months passed before a consistent succession of negative bacterial reports justified a clean bill of health.

I believe such an outbreak to be unique in public health records, and its lessons seem to be two-fold: 1. The careful examination in this respect of all new admissions. 2. That baths in barracks, boarding schools, and institutions should be mainly of the hot and cold shower type (both for individual safety and for water-waste prevention) with only such provision of "slipper" or "parallel" baths as may be necessary for medical and surgical reasons.

I am, Sir, yours faithfully,
CHARLES PORTER, M.D. R.U.I., D.P.H. Camb.,
Hon. LL.D. (Witwrd. Univ.), M.O.H. and Lecturer
on Public Health, Johannesburg.

*** The outbreak reported by Dr. Porter if not unique is sufficiently startling to require comment. The measures of prevention he suggests are sound and reasonable. Many little girls are carriers of gonorrhœa as a result of infection by towels, w.c.'s, and lavatories, and the youth of a child by no means precludes the possibility of her having gonorrhœa, though such sexual precocity as was found in Dr. Porter's case is rare. No towels, baths, or bedroom chambers should ever be shared by girl children in institutions. This should be a rule admitting of no exceptions. A similar outbreak observed this year at a convent home for older girls in a home county was traced to infection from one or more imperfectly cured cases of gonorrhœa by towels and baths. Facilities in this case were admittedly insufficient, as the institution, though well run in many ways, was short of funds.—ED. L.

THE HOSPITALISATION OF SEVERE TRAUMA ON THE SPOT.

To the Editor of THE LANCET.

SIR,—During the last few days the daily journals have described many a case in which an injured person, after an accident, has died on the way to hospital, or soon after admission. For long it has been my contention that movement, even for a short distance, is the worst possible treatment after any injury; shock is made greater; there is grave risk of injuring soft and vital parts; there is likelihood of re-starting loss of blood; there is serious danger of embolism; there are many possibilities of causing and increasing deformities.

An illustrative episode may serve to bring this home to those who have been schooled in the present regime. Last year I saw a severe injury—compound comminuted fracture of two limbs—nine days after the injury. During these days there had been a minimum of movement, the parts being left undisturbed; and at the end of that time the patient travelled a distance of about a mile from the scene of the injury, and came under my care at a cottage in the country. To my surprise I was able daily to manipulate the fragments into position without causing pain, and to get an ideal result. Not only so, but as the injury of one limb was adjoining the site of an old traumatic deformity, I was able to rectify that at the same time. The cost was trivial, and I did the nursing myself.

This incident confirmed my former conclusion of the wisdom of the advice: *Put a case of trauma into the nearest available bed.* The occupant of the house is not English—I had almost written British—if admission is refused. Some may argue that there is an absence of technical nursing in a rural house. But he is a poor over-schooled doctor who cannot quickly instruct a sister, or a neighbour, to nurse and manage everything well. The finest result that I ever saw after complete transverse fracture of the patella happened where a mother, unschooled but educable, tended her son in his home.

It may be urged that transport facilities are now such that there is no danger. That is just the sad fallacy of it all. Let a well person travel a distance of five miles in the most elaborately equipped ambulance, assuming the posture and position of a badly-injured patient, and he will quickly change his mental attitude towards the treatment of severe traumatism.

I am, Sir, yours faithfully,
R. CUNNINGHAM AFFLECK.

Edinburgh, June 30th, 1925.

A BELGIAN MEDICAL CRUISE.

To the Editor of THE LANCET.

SIR,—After all the causes for gratitude that the Belgian doctors, since the war, owe to the British doctors, the "Medical Days of Brussels," at which your Government was officially represented, have again drawn closer together the bonds which unite our two medical bodies. In these conditions, desirous of giving a tangible proof of our friendship, we have decided to invite our British colleagues to take part in a medical cruise to the Near East which we are organising. I shall be grateful if you will kindly insert the enclosed notice. Application may be made to me.—I am, Sir, yours faithfully,

Dr. R. BERNARD,
Secrétaire de la Rédaction, Bruxelles-Médical, 117, rue du Trône, Brussels.

July 1st, 1925.

Medical Cruise to the Near East: Itinerary.

Marseilles, Alexandria, Cairo, Port Said, Jaffa (Jerusalem), Beyrouth (Damascus–Liban), Smyrna, Constantinople, Le Pirée (Athens), Malta, Naples, Marseilles. Departure August 24th; return, Sept. 18th. Special conditions; 2700 French francs each for doctor and wife, 3600 French francs for each member of a doctor's family. The voyage is first-class by the large and luxurious packets *Cordillère* and *Lotus* Oriental mails. There will be an opportunity of visiting Cairo, Jerusalem, Damascus, and Athens, and of prolonging by 12 days the stay at Beyrouth in order to visit thoroughly Syria and Palestine. It will also be possible to visit Baghdad, three days by motor-car from Beyrouth.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—My attention has been called to a report in the *Daily News* of my annual hospital tea party. Although I was aware that the occasion was to be used for giving publicity to the hospital building fund, I had no knowledge that personal allusions were to be made to myself. I much regret that in the report references were made for which I am in no way responsible, and which are both undesirable and unnecessary. I am, Sir, yours faithfully,

London, W., July 4th, 1925. H. J. PATERSON.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Spahlinger Treatment.

THE Parliamentary Medical Committee met on July 2nd, to consider a report from five of its members who recently visited the establishment of Mr. Spahlinger at Geneva. The report commented favourably on the visit, and suggested that an effort should be made to raise £100,000 in this country by means of a public campaign to enable Mr. Spahlinger to continue his work. The Committee passed the following resolution:—

"That the Parliamentary Medical Committee has received with much interest the account of the visit to the Spahlinger establishment which the five members of the Committee have drawn up, not as a delegation from the Committee, but as private individuals. The Committee are of opinion that a prima facie case has been made out for further investigation, but the Committee resolve that they cannot as a corporate body take any action in the matter."

HOUSE OF COMMONS.

WEDNESDAY, JULY 1ST.

Night-work in Bakeries.

Colonel WOODCOCK asked the Minister of Labour whether His Majesty's Government proposed to take any step to refer to the Permanent Court of International Justice the question whether the draft convention in regard to night-work in bakeries proposed by the recent International Labour Conference, which related to an industry which was not the subject of international industrial competition and which prohibited night-work by master bakers as well as by persons employed, was consistent with the purpose of Part XIII. of the Versailles Treaty of Peace, and also the question of the competence of the conference to pass such a draft convention.—Sir A. STEEL-MAITLAND replied: This convention, as finally presented to the recent International Labour Conference, was not acceptable to His Majesty's Government, and their representatives voted against it. It is not the intention of the Government to take any further steps with regard to the convention in the direction indicated.

Persons Excluded from Pensions Bill.

Mr. TREVELYAN THOMSON asked the Minister of Health the approximate number of persons who, on account of their not being insured under the National Health Insurance Acts, would be excluded from all benefits under the proposed Pensions Bill, and the proportion which would be wage-earners.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: So far as the first part of this question is concerned, I would refer the hon. Member to Tables F and G on pp. 41 and 42 of the Government Actuary's Report on the Bill. These tables show in some detail the total population of each sex and the corresponding insured population. In regard to the second part of the question, the compulsory provisions of the Bill apply to practically all wage-earners who are either engaged in manual labour or are employed at rates of remuneration not exceeding £250 a year, and provision is being made for the continuance, on a voluntary basis, of the insurance of wage-earners who cease, or have already ceased, to be included in these categories.

The Use of Artificial Light.

Mr. Kenyon asked the Minister of Health whether, before sanctioning the setting up of institutions for the use of artificial light by local authorities, he would satisfy himself that a doctor experienced in this work was available.—Sir Kingsley Wood replied: The answer is in the affirmative.

THURSDAY, JULY 2ND.

Water Shortage at Saltash Hospital.

Colonel Day asked the Minister of Pensions whether, seeing that there was a shortage of water at the Ministry of Pensions Hospital for neurasthenics at Saltash, and that 450 patients and a large staff had not the necessary supplies, he would allow the patients to return home and continue to draw full treatment allowances.—Major G. C. Tryon replied: The temporary shortage of water which prevailed for a few days at Saltash Hospital has now disappeared. The supply for the last fortnight has been normal and is adequate for all requirements. I do not anticipate any further difficulty.

Closing of Oulton Hall Hospital.

Mr. Lunn asked the Minister of Pensions whether it had been decided to close the hospital at Oulton Hall, near Leeds; if so, on what date he proposed to close it and for what reason; was he aware that Oulton Hall was the only neurasthenic hospital in the county of York; that the hall and grounds had been given free to the nation by the owner to be used for this purpose; that there were 120 patients there, and a large number of ex-Service men who had received considerable benefit from treatment at this establishment; and that there was no other way in which they could be treated so economically; and would he reconsider his decision so as to allow the good work to proceed uninterruptedly.—Major G. C. Tryon replied: In view of the continuous decline in the number of pensioners requiring the kind of treatment provided at Oulton Hall it has been decided, after a careful review of the position throughout the country, to close this hospital (where there are at present 84 patients, only 42 of whom are drawn from the county of York) at or about the end of this month. In arriving at this decision, the points mentioned by the hon. Member have not been overlooked, but I have had to keep in view the general requirements and the necessity for making the most efficient and advantageous use of the facilities for neurological treatment at my disposal, having regard to the reduced number of cases to be dealt with and their distribution over the country as a whole.

Night-work in Bakeries.

Mr. Trevelyan asked the Home Secretary what the figures were of the final vote in favour of the ratification of the convention for the abolition of night baking at the International Labour Conference; how many of the votes adverse to ratification represented governments and which governments; how many represented the employers; and how many the workers.—Sir W. Joynson-Hicks replied: The figures at the final vote showed 81 in favour of the draft convention and 20 against. Of the adverse votes, three were given by delegates representing the British and Indian Governments, and the remainder by employers' delegates. There were a considerable number of abstentions.

Medical Inspection of School-children.

Mr. Briant asked the President of the Board of Education whether the Board had taken any steps to enforce the provision of medical inspection for the detection and correction of visual defects in those schools under the 14 local education authorities which the chief medical officer of health, in his report of 1923, stated make no such provision.—Lord E. Percy replied: I am glad to say that of the 14 local authorities in question six have, since the report was issued, provided for visual treatment, and seven others have submitted proposals for such provision. In the remaining case I am advised that any treatment which may be required can be obtained without special provision being made by the authority.

Compensation for Mr. W. S. Harnett.

Lord Henry Cavendish-Bentinck asked the Minister of Health whether he would advise the Government to pay to Mr. William Smart Harnett an adequate sum in compensation for his wrongful detention in various mental hospitals, having regard to the fact that Mr. Harnett had been found by a jury to have been sane when detained by Dr. Bond and for the rest of his detention, that this opinion had not been upset by either the Court of Appeal or the House of Lords, by which tribunals Mr. Harnett's case had been heard, and having regard to the fact that, although having thus been found to be sane, Mr. Harnett was to-day practically a ruined man on account of the legal expenses of the three actions in which he was concerned and the heavy expenses of his confinement, in all a sum of over £25,000.—Mr. Neville Chamberlain replied: I do not think that any claim for compensation out of public funds can be substantiated in this case. In any event, no servant of the Crown was involved other than Dr. Bond, and, as my noble friend is no doubt aware, a new trial has been ordered against Dr. Bond, and the matter is therefore still sub judice. I must not, however, be taken as admitting that the question accurately states the facts, for I observe that the Lord Chancellor in his judgment dismissing Mr. Harnett's appeal expressly pointed out that it was not in fact proved at the trial, nor found by the jury, that the appellant was of sound mind between the date of his alleged detention by Dr. Bond and his subsequent escape from custody.

Ophthalmic Benefit.

Mr. Bennett asked the Minister of Health whether he was aware that, as a result of the new model scheme for the provision of ophthalmic benefit by approved societies, which stipulated that an applicant for the benefit must, at the cost of 1s., have obtained and furnished his society with a written recommendation from a panel doctor, the charge for the necessary ophthalmic examination of the applicant had increased from 5s., which was the fee paid to qualified opticians, to £1 1s., which was the fee charged by ophthalmic surgeons; and whether, in view of the satisfactory nature of the service heretofore rendered by qualified opticians, he would suspend the order until the Royal Commission on the disposal of the surplus funds of the various approved societies could investigate and report on the matter.—Mr. Neville Chamberlain replied: I am aware that the cost of ophthalmic benefit under the new scheme may, in certain cases, show an increase as stated by the hon. Member over the cost of optical benefit under the existing schemes, but there will be no charge for the insurance doctor's recommendation, and the new arrangements have been generally accepted by approved societies. It is impracticable to adopt the suggestion in the latter part of the question, inasmuch as the new schemes for societies and branches, valued as at Dec. 31st, 1922, are due to commence on Monday next.

High Infant Mortality at Market Drayton.

Mr. Griffith asked the Minister of Health whether he had seen a report of a recent meeting of the Market Drayton Nursing and the Maternity and Infant Welfare Associations, where Dr. Wheatley, the medical officer for Shropshire, alluded to the high infant mortality of Market Drayton, and said that the principal causes of the high rate of infant mortality were bad housing and ignorance, and that the remedies were education and better housing; and whether he would at once publish the report of his own medical woman inspector on Market Drayton, to show what was her view of the causes of, and remedies for, the high infant mortality.—Mr. Neville Chamberlain replied: The answer to the first part of the question is in the affirmative. As regards the second part, I would refer the hon. Member to the answer which I gave on this subject on May 11th.

Sewage Pollution of the River Lee.

Captain Garro-Jones asked the Minister of Health whether he was aware that the River Lee, which passed through thickly populated London districts, was at present badly polluted with crude sewage; that the pollution was now worse than it had ever been; that the state of the river was not only offensive to the many rowing clubs which used it but was detrimental to the health of the dense riparian population; that the powers under the Rivers Pollution Prevention Acts were, as respects this river, divided between the Middlesex County Council and the Lee Conservancy Board; and that most of the pollution originated from tributaries within the control of the Middlesex County Council; and whether he would consider the desirability of promoting a short Bill to make the Lee Conservancy Board the rivers pollution prevention authority for the whole length of the river and its tributaries, and immediately urging the urban districts in Middlesex and the Middlesex County Council, in the interests of public health, to cease discharging sewage into the River Lee and its tributaries.—Mr. Neville Chamberlain replied: I am aware of the unsatisfactory condition of this river. I am not satisfied that it would be desirable to promote a Bill as suggested. The right remedy is to obtain treatment and disposal of the sewage, and my efforts have been directed to that end. Two of the large local authorities are now spending large sums in improving their disposal works, and a Bill is now before Parliament for taking the sewage of two others into the London main drainage system. When these improvements have been effected, conditions should be very much better.

Birmingham Hospital Bill.

St. Mary's Church, Birmingham, and General Hospital Bill was read a third time.

FRIDAY, JULY 3RD.

Infant Death-rate in Bombay.

Colonel DAY asked the Under Secretary of State for India whether he was aware of the increasing practice in Bombay of women employed in cotton factories administering opium to their babies before proceeding to their work and that, as a result, the infant death-rate in Bombay was approximately two in three; and would he make representations to those concerned suggesting that opium be made less accessible.—Earl WINTERTON replied: I am aware of the practice, but not that it is increasing. The average annual figures of infant mortality from all causes for the three years from 1922 to 1924 was 411 per 1000, as compared with 624 in the previous three years. As regards the last part of the question, the Government of India have addressed inquiries to all local governments as to the extent of the practice referred to and the question of taking measures specially designed to check it; my noble friend proposes to await the results of these inquiries.

MONDAY, JULY 6TH.

Indian Medical Service.

Sir RICHARD LUCE asked the Under Secretary of State for India if the Government had yet arrived at conclusions as to the future of the Indian Medical Service; and whether it was their intention to carry out the proposals of the Lee Commission in this respect, especially in the matter of establishing provincial medical services the members of which would not be under the control of the Secretary of State.—Earl WINTERTON replied: The Government of India's proposals are now under the consideration of my noble friend the Secretary of State, who hopes to arrive at early decisions. Meanwhile I regret that I am unable to make any further statement.

Medical Services in Tanganyika.

Mr. BARCLAY-HARVEY asked the Secretary of State for the Colonies the amount spent on medical and sanitary services and research work by the Germans in Tanganyika in the year 1913; and what were the corresponding figures for the year 1923–24.—Mr. AMERY replied: Owing to the difference in the system on which the British and German estimates are presented, the comparison is by no means easy. The amount provided for the services referred to in the German estimates for 1913 is approximately £99,000, converting the mark at 20 to the £. But this does not include expenditure by certain local bodies to which grants were made for a variety of purposes, including expenses connected with hospitals and sanitation, which are not shown separately in the estimates. The amount provided for similar services in the estimates for 1923–24 was approximately £116,700, which included all expenditure on buildings.

Lieut.-Colonel JAMES asked if the right hon. gentleman was satisfied that the amount spent was sufficient to fight epidemic disease in Tanganyika.

Mr. AMERY: No, Sir; I should like to spend a great deal more.

New Tuberculosis Order.

Mr. ALBERT ALEXANDER asked the Minister of Agriculture whether he would have the draft of the Order he was proposing to make, directing the slaughter of cattle affected with tuberculosis on the lines of the Tuberculosis Order of 1914, placed in the Library of the House before the discussion takes place on the Diseases of Animals Financial Resolution.—Mr. WOOD replied: Yes, Sir; I hope to place a copy of the draft Order in the Library towards the end of the present week.

Food Preservative Regulations.

Sir ROBERT GOWER asked the Minister of Health whether he had received a communication from the Bakery Allied Traders' Association representing that the result of the proposed Public Health (Preservatives, &c., in Food) Regulations, 1925, would mean dearer food and an acute shortage of supplies, with actual starvation in sight should a national emergency arise; and whether he had any statement to make upon the matter.—Sir KINGSLEY WOOD replied: Yes, Sir, my right hon. friend has received the communication referred to, which has had very careful consideration. He cannot, however, admit that there is any substantial ground for the apprehension expressed in the latter part of my hon. friend's question.

Dirty Fruit from Turkey.

Dr. HADEN GUEST asked the Parliamentary Secretary to the Overseas Trade Department whether his attention had been called to the existence of dirty and insanitary conditions prevailing in the transport, handling, and packing of dried fruit at Smyrna, Anatolia, and to the rates of wages and conditions of labour of the workpeople employed; and whether he would make inquiry to determine what action, through the consular service or otherwise, was required to protect the consumer against dirt contamination and the Dominions fruit-grower against unfair competition.—Mr. A. M. SAMUEL replied: This matter has engaged the attention of the Ministry of Health and my department very fully for some considerable time, and I have been in frequent communication on the subject with both the Ministry of Health and H.M.'s Consul General at Smyrna. I will consider in conjunction with my right hon. friend what action it is possible to take after further reports, which I have called for, have been received from Smyrna.

Prohibition of Night Baking in Foreign Countries.

Mr. TREVELYAN asked the Minister of Labour how many European countries had already abolished night baking; and in how many of those countries there had been any resultant rise in the price of bread.—Mr. BETTERTON (Parliamentary Secretary to the Ministry of Labour) replied: The information available shows that legislation prohibiting night work in bakeries is in force in the following European countries: Austria, Belgium, Czecho-Slovakia, Denmark, Finland, France, Germany, Greece, Hungary, Italy, Netherlands, Norway, Poland, Soviet Russia, Spain, Sweden, Switzerland (two cantons). This legislation does not necessarily follow the lines of the convention recently adopted by the International Labour Conference. I am unable to state from the official records of retail prices which are available how far any rise which may have taken place in the price of bread in the respective countries is attributable to the operation of such legislation.

TUESDAY, JULY 7TH.

Miners' Phthisis.

Mr. DAVID GRENFELL asked the Secretary for Mines whether he was in a position to report upon the inquiries of his department into the incidence of miners' phthisis among men engaged in rock-drilling by the use of compressed air machines.—Colonel LANE-FOX replied: I am not in a position to give any general conclusions, for the inquiry in question was confined to three mines. But its result was to support the apprehension that, in those mines, rock-drilling may be dangerous to health. I have arranged for a more extensive inquiry to be put in hand at once. Meantime the inspectors are taking up the question of precautionary measures at the three mines.

State Contributions to National Insurance.

Mr. RHYS DAVIES asked the Minister of Health if he would give the ratio of State contributions towards the national health and widows', orphans', and old age pensions insurance schemes, respectively, based on each £1 benefit payable or on any other unit of calculation.—Sir KINGSLEY WOOD replied: As the hon. Member is aware the State contribution towards the National Health Insurance system is two-ninths of the expenditure on benefits, exclusive of the cost of central administration; including this item the State contribution is just over one-quarter. It is estimated that the State contribution to the new pensions system will be equal, on the average, to one-quarter of the expenditure on benefits in the first ten years of the scheme and that after this period it will be approximately two-fifths of the expenditure.

Food Preservatives Regulations.

Mr. ALEXANDER asked the Minister of Health when the Public Health (Preservatives, &c., in Food) Regulations were to be laid before Parliament; whether any alterations in the published draft were proposed; and, if so, whether information as to the nature of these alterations could be supplied to Members before the regulations were finally made and laid before Parliament.—Sir KINGSLEY WOOD replied: My right hon. friend hopes that the regulations will be laid before Parliament adjourns. Considerable modifications have been made in the original draft as a result of full discussion between my right hon. friend's officers and the interests involved. The actual coming into force of the regulations will be postponed to enable necessary adjustments to be made by the trades concerned, and during that period my right hon. friend would hope that a discussion might be arranged in this House if there is a general desire for it.

THE TUBERCULOSIS CONFERENCE.

THE eleventh annual conference of the National Association for the Prevention of Tuberculosis, under the chairmanship of Sir Arthur Stanley and Sir Robert Philip, was held this week at the Robert Barnes Hall of the Royal Society of Medicine, when upward of 500 delegates attended. The international character of the gathering was indicated by papers written by scientists from Austria and Denmark. Dr. V. Vorobieff, professor of tuberculosis at Moscow University, brought the good wishes of his Russian colleagues.

The subjects under discussion were Tuberculosis in Childhood and the Treatment of Tuberculosis by Sanocrysin. The conference was opened by Sir Kingsley Wood. It had been intended that Prof. Pirquet should have delivered the introductory address, but being prevented Dr. Richard Wagner, his first assistant at the Vienna Children's Clinic, read his paper. Prof. Pirquet analysed with remarkable clarity the statistics of tuberculosis given in the Registrar-General's annual report for 1922. In his turn Dr. Wagner gave an illuminating account of the mode of treatment employed at the Vienna Clinic, the chief features of which were the complete disregard of tuberculin therapy and the attention paid to the feeding of the tuberculous child. Food-scales had been worked out in relation to the sitting height of the children who were given larger quantities of food than healthy children of the same age. Stress was laid on the desirability of dealing with tuberculous children in their own homes; hospital accommodation could not possibly be provided for all the cases existing. A slide illustrating a practical wooden balcony for open-air therapy, attached to the window of an ordinary house, was shown.

Dr. A. Stanley Griffith, of the Field Laboratories, Cambridge University, emphasised the importance of dealing with the menace of tuberculous cows' milk; he thought that the general public was not sufficiently informed of the fact that bovine tuberculosis was an important source of human tuberculosis. Sir Henry Gauvain stigmatised the argument that drinking slightly infected tuberculous milk would enable children to acquire immunity to infection as a dangerous and unnecessary doctrine; even if it was proved to be correct there would be more scientific methods of imparting such immunity. Medical men would hesitate to eat infected oysters knowingly to immunise themselves against typhoid fever. Prof. J. Fraser, of Edinburgh, pointed out the large proportion of cases of surgical tuberculosis coming from country districts to the Edinburgh Children's Hospital; this he attributed to the ignorance of the cow-keeper of the harm done by tuberculous milk. Sir Percival Hartley expressed his entire agreement with all that had been said on the dangers of tuberculous milk and finally, at the instance of the (medical) chairman of the St. Helens Public Health Committee, a resolution was sent by the conference to the Ministry of Health urging the Government to render effective the provisions of the Milk and Dairies Act dealing with tuberculous milk.

Instructive accounts of the treatment of surgical tuberculosis at Alton and Carshalton were given by Sir Henry Gauvain and Dr. W. T. Gordon Pugh. Slides were shown illustrating the successful treatment of marked kyphosis at Alton by hyperextension. Dr. Pugh showed carriages on which a child could be satisfactorily immobilised during attention to its natural functions and the toilet of the hair. Pushed on these carriages the children were able to go out and see the shops and pay a visit to the cinema. He emphasised the importance of parents allowing their children to be sent to hospital in an early stage of the disease. Prof. Louise McIlroy pointed out the lack of coördination existing at present between the obstetrician and the tuberculosis physician; she wanted a sanatorium equipped with an obstetrical staff instituted near the borders of London for pregnant tuberculous women.

The last session was devoted to papers by Profs. Mollgaard and Knud Faber, of Copenhagen, and Prof. S. Lyle Cummins on the sanocrysin treatment. Sir Robert Philip expressed a guarded opinion that the ultimate outlook of this method of treatment is encouraging, and praised the scientific attitude taken up by Prof. Mollgaard, who had placed his knowledge at the disposal of the Medical Research Council. Emphatic opinions were expressed by hospital workers and tuberculosis officers on the folly of allowing advanced cases to take their discharge from institutions and so return home to infect the young children of the family.

Medical News.

UNIVERSITY OF LONDON, KING'S COLLEGE FOR WOMEN.—At the third B.Sc. examination in Household and Social Science held recently the following candidates were *successful*:—

Edna G. Allen, Margaret F. Brownlee, Zille G. Bull, Bertha M. Grainger, Grace J. Helps, Hyacinth E. Kirman, Nancy H. Knowles, Elspeth M. Marshall, Helen E. Ross, Dorothea V. C. Story, Enid C. Strange, Annie Sutcliffe, and Mary M. G. Wright.

UNIVERSITY OF OXFORD.—The following candidates passed in the recent Final Examination for the degrees of B.M. and B.Ch.:—

Materia Medica and Pharmacology.—Howard W. Allen, Merton; Ormond A. Beadle and Denis H. Brinton, New; Conal Charleson, Queen's; Henry E. Cuthbert, St. John's; Johannes G. A. Davel, Trinity; Walter N. Dickenson, Pembroke; Hugh R. J. Donald and Cecil W. Flemming, Trinity; Kenneth A. Hamilton, Christ Church; Reginald A. Haythornthwaite, Keble; Otto Hooper, University; Charles W. Hope-Gill, Queen's; Stanford Howard, Christ Church; George L. M. Inkster, Balliol; Arthur J. Leslie-Spinks, Oriel; George E. Macdonald, New; Robert G. MacGregor, Worcester; Patrick C. Mallam, Queen's; Ripley Oddie, Oriel; Robert Okell, Christ Church; Malcolm G. Pearson, Keble; Jack W. Pugh, University; Hill G. Wells, Magdalen; and Edward M. B. West, New.

Pathology.—Ormond A. Beadle, New; Louis W. H. Bertie, St. John's; Denis H. Brinton, New; Wilbert H. Brown, Queen's; Noel Chilton, Brasenose; John H. Chitty, New; Alan W. Cubitt, Wadham; Eric L. Fothergill, Keble; Alan C. Gairdner, University; Arthur H. Gale, Trinity; Thomas B. Hodgson and Charles W. Hope-Gill, Queen's; Alfred Kendrew, Christ Church; James H. Kennedy, Magdalen; David Lurie, Lincoln; Clifford E. Roberts, Jesus; Richard W. A. Simmons, Oriel; Edward M. B. West, New; Arthur G. Wilson, Brasenose; Rosalind V. Carruthers and Margaret A. L. Herbertson, Society of Oxford Home Students; Margaret N. Jackson, Somerville; Kathleen G. Norton, St. Hugh's; and Irene M. Titcomb, Society of Oxford Home Students.

Forensic Medicine and Public Health.—Douglas A. Abernethy and Eric N. Allott, Balliol; Frank J. Bach, New; Robert B. Bourdillon, University; Hugh N. Bradbrooke and Clarence S. Broadbent, Queen's; Albert V. Clemmey, Christ Church; Charles R. Croft, Trinity; John N. C. Ford, Hertford; Samuel Harris, Jesus; Thomas B. Hodgson, Queen's; Alfred Kendrew, Christ Church; Raymond Lewthwaite, Magdalen; Thomas M. Ling, New; Gerald L. M. McElligott, Hertford; William D. B. Read, Magdalen; Clifford E. Roberts, Jesus; Richard W. A. Simmons, Oriel; John W. de W. G. Thornton, Magdalen; George P. Thorold, Trinity; Oliver R. Tisdall, Hertford; Arthur L. Wilkinson, Trinity; William R. Wood, Pembroke; Hon. Olive B. Buckley, Somerville; Kathleen G. Norton, St. Hugh's; Janet M. Vaughan, Somerville; and Rosa S. Wordsworth, Lady Margaret Hall.

Medicine, Surgery, and Midwifery.—Douglas A. Abernethy and Eric N. Allott, Balliol; Robert B. Bourdillon, University; Hugh N. Bradbrooke, Queen's; John S. Jerome and Alfred Kendrew, Christ Church; Eric L. Newell and Clifford E. Roberts, Jesus; Victor P. Robinson, St. John's; John G. S. Thomas, Hertford; Robert A. Walsh, Magdalen; Evelyn C. Whitehall-Cooke, Queen's; Hon. Olive B. Buckley, Somerville; Ella J. Cockram, Society of Oxford Home Students; and Janet M. Vaughan, Somerville.

The following Theodore Williams Scholarships have been awarded: In Physiology, F. Hawking (University Coll.); in Human Anatomy, J. M. Gibson (University Coll.); in Pathology, O. A. Beadle (New Coll.). The Welsh Memorial Prize for Anatomical Drawing was awarded to J. H. B. Beal (scholar of University Coll.). The Radcliffe Scholarship in Pharmacology was awarded to K. A. Hamilton (Christ Church). Recent elections by external bodies:—To a Commonwealth Fund Fellowship: B. G. Scholefield (Christ Church and Guy's Hospital); to Rockefeller Medical *Fellowships*: W. S. Dawson (Trinity Coll.), H. W. Florey (Magdalen Coll.), and G. P. Wright (Exeter Coll.).

Royal College of Surgeons of England: Election of Council.—The annual meeting of Fellows of the Royal College of Surgeons to elect three members of the Council was held on July 2nd, the President, Sir John Bland-Sutton, Bart., in the chair. There were seven candidates for three vacancies. The President declared the following three Fellows to be elected :—

	Votes.	Plumpers.
Arthur Henry Burgess	462	48
James Sherren	441	14
Sir John Lynn-Thomas	406	7

The other candidates were :—

Victor Bonney	361	19
Vincent Warren Low	332	12
John Percy Lockhart-Mummery	243	11
Herbert John Paterson	232	18

The President further declared that 964 Fellows had voted, 961 sending ballot-papers through the post, and 3 voted in person. Three invalid ballot-papers were received. Mr. H. J. Price (of Maldon) and Mr. Wilmott Evans (of Harley-street) were the scrutineers.

Liverpool's New Hospital for Women.—At a well-attended meeting held at Liverpool on June 29th approval was given to the scheme for the amalgamation of the Hospital for Women (Shaw-street) and the Samaritan Hospital, and authority was given for the issue of a public appeal for £80,000, which, with the £40,000 already in hand, will make up the £120,000 estimated for the new building and its equipment. Both of these hospitals have a large record of usefulness, but the present buildings—with 85 beds—are out of date. The new scheme will provide 120 beds. At the meeting promises of subscriptions to the amount of £10,000 were announced, including £5000 from the sons of the late Alderman Cohen, £1000 each from Sir Charles Nall-Cain and Lieut.-Colonel Campbell N. Watson, D.S.O., £600 from Mrs. J. R. Hughes, and £500 each from Sir William Forwood and Sir Richard Caton, £250 each from Messrs. Balfour, Williamson and Co. and Mr. Frank Minoprio, and £200 each from Dr. Gemmell, Mr. Archibald Crawford, and Messrs. Wm. Crawford and Sons, Ltd.

Fellowship of Medicine and Post-Graduate Medical Association.—A late afternoon course in the Diagnosis and Treatment of Common Diseases of the Nervous System has been arranged by the West End Hospital from July 27th to August 14th. The lectures and clinical demonstrations will be given in the out-patient department at 73, Welbeck-street.—A vacation course will be held at the Prince of Wales's General Hospital (North-East London Post-Graduate College, Tottenham) from August 4th to 15th. The daily sessions from 10.30 A.M. to 5.30 P.M. will include lectures and demonstrations in all branches of Medicine and Surgery and in the Special Subjects, including Mental Diseases and Fevers, the first of which will be by Mr. Lockhart-Mummery. The formal lecture, at 4.30 P.M., will be free to members of the Fellowship of Medicine.—From August 24th to Sept. 5th the Queen Mary's Hospital, Stratford, will give an intensive course, when lectures, demonstrations, ward rounds, operations, &c., will be demonstrated in the various departments of medicine, surgery, and the specialties.—The following special courses will take place in September: Diseases of the Chest, Infants, Dermatology, Electrotherapy, Ophthalmology, and an intensive course at the Westminster Hospital.—Copies of the syllabus of each of the above-mentioned special courses and the programme of the Fellowship of Medicine will be sent on application to the Secretary at 1, Wimpole-street, London, W. 1.

Irish Medical Association: Annual Meeting.—The annual meeting of this Association was held on June 25th at the Royal College of Surgeons in Ireland, Senator W. O'Sullivan, M.D., President, in the chair. There was only a fair attendance of the 456 members on the books of the Association on Dec. 31st, 1924. Prof. F. C. Purser, of Dublin, and Dr. H. T. Warnock, of Donegal, were unanimously elected President and Vice-President. Prof. Purser, in his presidential address, pointed out that an overwhelming body of medical opinion in Ireland was in favour of the continuance of the present system of medical registration. It was not inconsistent with their national aspirations, because no pressure was put on them to continue as they were, and they could end their coöperation with the General Medical Council at the termination of any agreement come to between the Irish and English Governments. Economically, it was true, they were training many able men and women who could not hope to earn a living in Ireland, but the solution of this did not lie in setting up an Irish Medical Council. These young men and women intended to join the profession anyhow, and if they could not get trained in Ireland they would get trained elsewhere, to the great loss of Dublin, Cork, and Galway.

Royal Institution.—A general meeting of the members of the Royal Institution was held on July 6th, Sir James Crichton-Browne, Treasurer and Vice-President, in the chair. The special thanks of the members were returned to the Delegacy of the City and Guilds (Engineering) College for their valuable gift of micro-photographic apparatus. Mrs. Romanes and Dr. R. A. Young were elected members.

Nursing and Public Health.—At the annual meeting of the Manchester and Salford District Nursing Institution held on June 30th Dr. R. Veitch Clark, medical officer of health for Manchester, spoke of the way in which the associations and the public health authorities might be most usefully developed. It was in dealing with diseases of young children—measles, whooping-cough, bronchitis, and bronchial pneumonia—that the practice of curative and that of preventive medicine were closely interlinked. Nursing associations were primarily established for the care of those who could not themselves afford to pay for nursing, and indeed a large part of the work of their association was confined to such cases. Between the very poor and the rich there were two classes, represented by the wage-earners under the National Health Insurance Act and by the group immediately above this class who were not wealthy, but reasonably comfortable. Dr. Clark outlined a scheme whereby the families of the "reasonably comfortable" group could obtain cheap nursing benefits. Employees at private firms would contribute 1*d*., 2*d*., or 3*d* a week to the Nursing Institution and receive in return any nursing that from time to time they might require. The contributions could be paid weekly or monthly, according to the amount of nursing desired, or a definite charge could be paid for the daily visits of the nurse as required. The scheme, he said, was a practical one; before he came to Manchester he had established one elsewhere on similar lines and it was running successfully.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, July 13th, to Saturday, July 18th.—Queen's Hospital for Children, Hackney-road, E. Special Course in Diseases of Children daily from 10 A.M., morning and afternoon sessions covering demonstrations, ward round, out-patient departments, and operations (second week).—St. Peter's Hospital, Henrietta-street, W.C. Special Course in Urology. Clinical work every afternoon throughout the week. Lectures: Monday, Mr. J. Swift Joly: Tumours of the Urinary Tract; Tuesday, Mr. Swift Joly: Urinary Calculi; Wednesday, Mr. Clifford Morson: The Relationship of Urology to Group Medicine; Thursday, Mr. F. J. F. Barrington: Non-tuberculous Infections of the Urinary Tract; Friday, Sir John Thomson-Walker: Urinary Obstruction.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, July 13th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Donald Armour: Operations.

Tuesday.—11 A.M., Dr. McDougal: Electrical Dept. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept. 3 P.M., Dr. Pritchard: Medical Wards.

Wednesday.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Dowling: Skin Dept.

Thursday.—11 A.M., Sir Henry Simson: Gynæcological Wards. 12 noon, Dr. Pritchard: Modern Methods of Medicine. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

Friday.—10 A.M., Sir Henry Simson: Gynæcological Operations. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, July 14th.—4.30 P.M., Mr. N. B. Fleming: Fundus Changes as an Index of General Diseases.

Friday.—4.30 P.M., Mr. W. E. Tanner: Surgical Aspects of Tuberculous Mesenteric Glands.

Daily: In- and Out-patient Cliniques, Operations, Cliniques in Special Departments, &c.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

Thursday, July 16th.—5 P.M., Mr. Leslie Williams: Toxæmia of Pregnancy.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, July 16th.—4 P.M., Dr. Thursfield: The Treatment of the Asthmatic Child.

Appointments.

FAULKNER, H A, M R.C.S., L.R C P Lond, B V Sc, has been appointed a Member of the Honorary Medical Staff of the Willesden General Hospital

GILMOUR, J., M.S Durh., F R.C.S Eng, Hon. Assistant Surgeon, Royal Victoria Infirmary, Newcastle-on Tyne

Royal Northern Hospital, Holloway CALVERT, I E. G B, M.D, M R.C.P, Physician with charge of Out patients; *LANE ROBERTS, I C. S, F R C.S, Obstetric Surgeon with* charge of Out patients

Births, Marriages, and Deaths.

BIRTHS.

BROWN—On June 29th, at "Kingslea," Sutton, Surrey, the wife of Dr C. Carron Brown of a son

LODGE.—On July 2nd, at Heath Hall, Halifax, Yorkshire, the wife of W O Lodge, M D, F R.C.S. Edin, of a daughter

MARRIAGES

NICHOLLS—SCHUSTER.—On July 2nd, Marriott Fawckner Nicholls, B.A., M.R.C.S, L.R.C P, son of the late Marriott Nicholls, Esq, to Norah Henriette Schuster M.B, Ch.B., daughter of Sir Arthur Schuster, Kt., F R.S

THOMAS—RICKS.—On July 1st, at the Parish Church, Cockington, Torquay, by the Rev H Studdy, M A. Clement Price Thomas, F R.C.S., to Ethel Doris, daughter of Mr and Mrs Mortimer Ricks, Paignton, S Devon

DEATHS

FRASER.—On June 30th, Evan J H Fraser, M.D, F R C.S. Edin., of Hull.

HARFORD—On July 4th suddenly, at Shirky, Harpenden, Charles Forbes Harford, M.D, First Principal of Livingstone College, aged 60

HOVELL.—On June 30th, Thomas Mark Hovell, F R.C.S., of Harley-street and Hatfield, Herts, aged 72

N B—A fee of 7s. 6d is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE ARTIFICIAL SUNLIGHT CLINIC AT KINGSTON-UPON-HULL

THE first municipal clinic to be established in this country for the treatment of rachitic children by artificial sunshine was opened last year at 60, Collman-street, Hull. A few months later the city of Liverpool after sending a deputation to Denmark, set up at their Fazakerley Sanatorium an installation for the treatment of tuberculosis of the bones and joints. The first municipal clinic in London for the provision of treatment by artificial sunlight was opened in St Pancras during March, and several other clinics are now running in the metropolis.

Procedure at the Hull Clinic.

A report of the Hull clinic has just been published by Dr W. Allen Daley, medical officer of health, and Dr. Kathleen Gamgee, assistant medical officer for maternity and child welfare The infants are weighed and measured, their history taken, and their blood tested for hæmoglobin content in rooms on the ground floor The sunlight treatment is given in a small room (15 feet by 12 feet) on the first floor Two or three mothers can wait in a small dressing room adjoining the treatment room The period of exposure of each patient to the ultra-violet rays varies from 3 to 15 minutes One child only is treated at a time, and is held, without clothing, in front of the arc lamp by a nurse Another nurse controls the arc lamp, and a third nurse is engaged downstairs. Dr Gamgee is responsible for the ordering of the time of exposure required for each child, and attends the clinic whenever it is open. The lamp, had it not been presented to the corporation, would have cost about £35; renewal of electrodes has cost £9 16s 10d., and electricity 18s 9d

During the year 110 patients have been treated at the clinic. The children for treatment were selected by the health visitors who, in the course of their home visits, discovered rickety children who had not in most cases attended a maternity and child welfare centre These children were examined by the assistant medical officer, and if she considered them suitable for treatment they were put upon the waiting list for the artificial sunlight clinic. In the meantime they were given advice with regard to diet and general hygienic treatment, the routine being to prescribe pure cod liver oil and one pint of milk per day for each child, and, in severe cases daily tepid sponging and gentle massage by the mothers until the child can be transferred from the waiting list to the artificial sunlight clinic. This treatment has improved the health of the child in cases where the mother is persevering and intelligent, *but improvement effected in this way is far more gradual and altogether a slower process than the dramatic changes seen at the artificial sunlight clinic*

Each child is subjected on its first attendance to a careful and prolonged physical examination It is weighed and measured and its blood tested The dosage for each child *is small at first and increased very* gradually It is remarkable how little skin reaction some of these babies give to doses that quickly cause the skin on an adult to peel The browning produced by the tungsten arc is not great *Many of these babies become browner after* the treatment. They lose their transparent anæmic look, become livelier, and at the same time more peaceful. The first improvement is usually registered by the mother who states, of her own accord, that her baby is more active, but at the same time sleeps more and is far less trouble at home One of the cardinal symptoms of rickets is the nervousness and irritability of the small patient. It is one of the first symptoms to yield to the artificial sunlight cure properly administered Another point to note is the rapidity with which the marked anæmia yields to the ultra violet radiations. Out of 88 cases only 10 cases (four of them cases of grave organic disease) showed no increase in the percentage of the hæmoglobin (red *colouring* matter) of the blood In one case, that of a delicate and very anæmic little girl of 4½, who had been under prolonged treatment by private doctors and had been under treatment for some time at the Owen Hall centre, the Hb percentage *increased by 100* per cent at the end of *her six weeks' course*

The estimation of the hæmoglobin percentage is most conveniently done by Tallquist's method Although not a scientifically reliable method, it is a good working scale if done by the same person each time, and it has the advantage of simplicity and quickness and of not alarming the baby more than is absolutely necessary

Classification and Results

Up to the time of reporting 110 patients have been treated at the clinic; 24 are still under treatment, and of the remaining 86, 18 were discharged: because of irregular attendance, 7; development of infectious illness, measles, &c., 10; extreme fretfulness of child, 1.

The remaining 68 cases are divided into the following classes:—

(1) *Severe Rickets:* These cases include some with marked deformity, others with less marked although still obvious deformity, but with severe impairment of general health.

(2) *Slight Rickets:* Including cases of rickets with slight bony deformity.

(3) *Wasting Babies:* No definite rickets.

(4) *Other Conditions.*

(5) *Infantile Paralysis* (anterior poliomyelitis).

The following table sets out the results of treatment:—

—	Number treated.	Much improved.	Improved.	No. change.	Worse.
Severe rickets ..	31	19	10	2	0
Slight rickets ..	22	15	5	2	0
Wasting babies.	6	5	1	0	0
Other conditions	8	0	4	4	0
Old anterior poliomyelitis ..	1	0	0	1	0
—	68	—	—	—	—

Eight cases admitted as suffering from malnutrition or rickets and found to be suffering from grave organic disease (such as kidney disease, tuberculosis, heart disease) were transferred to the children's hospital or to their private doctor. There was a satisfactory attendance, even from those who had to come on two trams, and this indicates that the parents at all events are convinced that their children are improved by treatment at the clinic. The keenness and interest of the mothers is remarkable, and the percentage of cases that have had to be cancelled owing to irregular attendance is very small and is decreasing with each batch of cases treated.

Repeat Courses.

In every case where it is felt that the condition of the child demands it, a repeat course, or even two or three repeat courses (of six weeks' duration each) are given. Experience has taught that it is better to allow an interval of six weeks to elapse before the second repeat course is given. It is very noteworthy how much the child continues to improve in the weeks immediately following the first course of treatment. Re-examination of old cases showed that not only had the good condition of the child been maintained throughout several months, but that it had gone on improving, and the hæmoglobin percentage had not gone down, but had maintained the high level reached at the end of the course of treatment.

Requirements of a Sunlight Clinic.

The treatment is now well beyond the stage of trial; arrangements should be made for making it more readily available for all who require it, including not only rachitic and wasted infants, but also cases of tuberculosis of the bones and joints.

The accommodation which would be necessary in a fully equipped artificial sunlight treatment centre would be two rooms for carbon arc treatment—one for males and one for females—and either two large rooms or a number of smaller rooms in which treatment could be given by the tungsten arc and by mercury-vapour lamps. A waiting room would be necessary; also a recovery room, in which the patients could remain after treatment; a medical examination room; a record room; a nurses' room; and an X ray room with developing room and film room attached. Sanitary accommodation for patients and staff would also be required. The staff which would be necessary for a fully developed centre would be a whole-time medical officer, four or five nurses, a clerk, and a porter.

The cost of the electrical apparatus and wiring of the fully developed clinic would be approximately £1000 and an additional £1000 would be required for furnishing. Further cost, of course, would be entailed by the purchase or rent of the building and its adaptation. At first the medical staff need consist only of the services of a part-time medical officer who might train a junior member of the profession, who would eventually be able to take full charge. The other staff, which would be required at first, need not consist of more than two or three nurses, with the necessary clerical assistance.

THE ASFURIYEH MENTAL HOSPITAL.

BEFORE the opening of the Lebanon Mental Hospital at Asfuriyeh the treatment of mental disease in Syria was entirely in the hands of native priests and exorcists whose cruel and ignorant methods usually aggravated greatly the sufferings of their unfortunate victims. Theophilus Waldmeier, the founder and first superintendent of the above hospital, had a remarkable career. Born in Switzerland, he passed from Roman Catholicism, through ecclesiastical Protestantism to Quakerism. He was a missionary to Abyssinia in the days of King Theodore, whose friend he became. He suffered imprisonment at the hands of the king and for a time his life and that of other prisoners was in grave danger. From Abyssinia he passed to Syria, where, on Mount Lebanon, he eventually founded the Friends' Syrian Mission, turning from that, after some 25 years, to the founding of the mental hospital.

The twenty-sixth annual report of this institution records considerable financial difficulty in carrying on the work, many old supporters having been lost by death. During the year 141 patients were admitted, making a total of 228 under care, and there has been a gratifying freedom from accident and infection. Every effort is made to keep the patients occupied and an electro-therapeutic plant has been installed. The dementia præcox and manic-depressive groups of psychoses account for the vast majority of admissions, and in Syria, as in this country, the principal causes assigned for the mental breakdown are mental stress, syphilis, and heredity. The recovery-rate is 21 per cent., with a further 15 per cent. discharged relieved.

THE TRAINING OF HEALTH VISITORS: CENTRAL EXAMINING BODY.

ON April 1st last the administration of Exchequer grants for the training of health visitors was transferred from the Board of Education to the Ministry of Health. The conditions on which grants are now made by the Minister of Health were set out in THE LANCET of Feb. 21st (p. 420). Students will be required to enter for an examination to be conducted by a central examining body, and the Minister has now approved the Royal Sanitary Institute as this examining body. The Institute will conduct the examinations for health visitors in accordance with the conditions prescribed in Memo. M.C.W. 101, and will issue certificates to candidates who pass the examination and who satisfy the other conditions specified in the memorandum. The diploma issued to students who, before April 1st, 1925, began a course of training approved by the Board of Education, will be regarded as equivalent to the health visitor's certificate. Communications should be addressed to the Secretary, The Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W. 1.

THE MISSION TO LEPERS.

FOUNDED in 1874, the Mission to Lepers has now published its fiftieth annual report. Nearly 8000 lepers are being supported wholly or partly by the funds of this mission, and over 700 untainted children are being kept and educated in separate homes. The nature of the work has wholly changed since its inauguration owing to the curative treatment now possible. The new treatment is being given at an increasing number of the homes and many lepers have been discharged cured. Dr. R. M. Wilson reports from Korea that chaulmoogra oil and camphor have been found to give better results than the esters. The importance of treating predisposing causes such as hookworm, typhoid, syphilis, and kala-azar is being increasingly realised. The chief need is to find some way of attracting the early cases; a small patch of anæsthesia is liable to be concealed because of the ostracism that must follow its discovery. The Mission has appointed a special secretary for medical work, Dr. Robert G. Cochrane. During the last year Dr. Thomas Cochrane has conducted a world survey of leprosy, which has emphasised the urgent need for new work in Africa.

THE GROWTH OF A HOSPITAL.

IN support of the appeal for the extension of the nurses' home of the Manchester Royal Infirmary an interesting illustrated booklet has been issued setting forth the various stages in the growth of the infirmary. There is a picture of "The Publick Infirmary" in Manchester, opening on the 24th day of June, 1752, and this is followed by a view of the "Daub Hole Fields Infirmary" as it appeared in July, 1755. Then follow pictures of the "Old Infirmary" and its successor. A comparison between the staffs and patients in July, 1752, and in 1924 is shown in the following table:—

	1752.	*1924.*
Beds	12	750
Medical staff non-resident ..	—	23
Nurses	1	233
Porters	1	21
Domestic staff	1	141
In-patients	75	12,386
Out-patients	249	42,318

DONATIONS AND BEQUESTS.—Mr. Solomon Whitta, Bowes-park, N., who left estate valued at nearly £11,000, bequeathed the bulk of the estate for equal division between the London Hospital, St. George's Hospital, the Royal Northern Hospital, Holloway-road, N., and the Hospital for Women, Soho-square, W.C.

New Research
INTO THE
ORIGIN OF CANCER.

[The two communications which follow mark an event in the history of medicine. They form a detailed description of a prolonged and intensive research into the origin of malignant new growths, and they may present a solution of the central problem of cancer.]

THE ÆTIOLOGY OF MALIGNANT NEW GROWTHS.

By W. E. Gye, M.D. Edin.

(From the Medical Research Council's Field Laboratories, Mill Hill, N.W.)

Introduction.

In 1911 Peyton Rous[1] described a sarcoma of the fowl which differs from mammalian tumours in one very important way—namely, that it can be transferred from chicken to chicken by inoculating dead cells, killed by drying or with 50 per cent. glycerol, or by means of a cell-free Berkefeld filtrate. The mammalian tumours, with the possible exception of a lymphosarcoma of dogs,* have so far been transferred only by inoculating living cells. This chicken tumour —No. I. in the series examined by Rous—is a spindle-celled sarcoma which metastasises freely and generally kills the host within 28 days. The malignancy of the tumour has increased with passage. It cannot be transferred to mammals or to any other species of birds than the hen, either by inoculating living cells or filtrates. Its specificity at first was exceptionally strict; successful transplantations of the tumour could be obtained only in blood relations of the bird—a Plymouth Rock—in which the original tumour occurred. The tumour now grows freely in other varieties of fowls, but the Plymouth Rock is still by far the most suitable variety of bird for experimental study.

A second filterable tumour of the hen was described by Rous[2] in 1912 (Tumour VII.). This tumour is an osteochondrosarcoma. The primary growth was benign, but it proved to be transplantable and with repeated passage became malignant. It differs from tumour No. I. not only in its histology, but also in its general behaviour, rate of growth, site of metastatic deposits, &c. It can be transferred with dead cells or with filtrates.

The third of these filterable tumours—No. XVIII.—was described by *Rous in 1914.*[3] *It* is a spindle-celled sarcoma with blood sinuses into which growth occurs. The tumour may be propagated with living cells, or with Berkefeld filtrates, but not by means of the dried tumour.[4]

There are, then, three well-described filterable tumours—all sarcomata and all growths of hens—among many thousands of animal tumours which have been transplanted and studied. It is very improbable that every neoplasm which has been described has been tested thoroughly as to its filterability, and it is therefore possible that one or more filterable tumours have been overlooked. But the general statement may be made: First, that no mammalian tumour has been propagated by cell-free filtrates; secondly, that a large number have been tested with entirely negative results; and thirdly, that if filterable mammalian tumours occur they are exceptions to the general rule. Thus the filterable chicken sarcomata differ, apparently, fundamentally from other tumours. This difference has led to expressions of doubt as to their being true new growths. It is unnecessary to discuss this point, as the work to be described will show, but it must nevertheless be pointed out that Rous studied the filterable tumours most carefully and showed clearly that they answer every valid test which has been put forward as a criterion of new growths. Indeed, no set of tumours has been more thoroughly studied from this point of view. In my judgment the classical papers published by Rous between 1911 and 1916 settled this point conclusively.

The problem which remained when Rous concluded his work on these tumours was the determination of the nature of the filterable agent. Rous and his collaborators brought forward strong evidence in favour of its being a filterable virus—a living but extremely small microbe. Thus the agent is destroyed by exposure to a temperature of 55° C. for 15 minutes; by chloroform and toluene; by phenol in concentrations as low as 0·5 per cent., and by other antiseptics; and the tumour may be kept immersed in glycerine and it still retains its infectivity. In spite of this evidence Rous used the term "agent" rather than "virus," since the final proof that the agent is animate its cultivation outside the body was missing.

The work which is to be described in this paper began with the study of chicken sarcoma No. I. Before plunging into details of this work a few words on the parasitic hypothesis of the origin of tumours may not be out of place.

The "parasitic hypothesis" of cancer may be stated briefly as follows: Malignant new growths constitute a specific disease and have as their essential cause a specific parasite. To some advocates the parasite is a microbe—e.g., the *Micrococcus neoformans* of Doyen; to others a protozoon; to others again, it is a new form of organism which is capable of existing as "unorganised plasm," as a filterable virus, in coccal or bacillary forms or as a fungus.

The opponents of the parasitic hypothesis—and they are chiefly those who have devoted themselves to cancer research—have no difficulty in refuting the theory in the form in which it has been presented. In the first place there has been no agreement amongst the advocates as to which of the many organisms brought forward as the "cause" of cancer is the true one; and in the second place it has never been possible to reproduce a tumour with a culture of any one of the organisms. Further, when all the definite knowledge we possess on malignant disease is arranged in due order an impressive case can be made out against the general conception that malignant disease has an extrinsic specific cause. The evidence, however, is largely negative, and is really only destructive of the view that tumours are the pathological consequence of the simple conjunction of host and parasite.

The Rous group of filterable tumours has been an embarrassment to both sides. Those who oppose the parasitic hypothesis have been content either to regard these tumours as entirely exceptional—a view that by implication rejects the concept of new growths as a homogeneous, specific disease and places them as a consequence amongst the inflammations—or to deny that the tumours are true new growths. Those who favour the parasitic hypothesis have inclined to ignore the Rous tumours for different reasons; these tumours make the theory too complicated altogether.

One of the outstanding features of new growths is their specificity. A tumour of the mouse, transplanted in fragments of living cells, will not grow in the rat or vice versa. The species specificity is very strict.

---

* During the year 1924 I collaborated with the late Dr. B. R. G. Russell in the study of this tumour. The work has been continued in conjunction with Dr. A. M. Begg, and the results will be given in another paper.

It may be argued that this is probably an example of general cellular specificity and is therefore not a particular property of tumour cells. And the argument is probably sound. But cell-free filtrates of the chicken sarcomata are just as strictly specific; they are incapable of producing a tumour in any bird save the hen, and much less in a mammal. Moreover, the filtrate from each tumour reproduces only a tumour of the same structure and general behaviour as that from which it is derived. The specificity, in other words, applies not only to the species but even to tissues. If we accept the conclusion that these tumours are caused by living viruses and argue—justifiably—therefrom that other tumours have similar causes, we are inevitably driven, in the present state of knowledge, to the conclusion that for every species of animal there is at least one group of viruses and for every tissue a particular virus. We are thus led by the logical application of undisputed facts to an apparently absurd position. It does not require a penetrating insight into pathological problems to see that an essential fact is missing and that its discovery may be the key to the general problem of tumours.

This strict specificity, to which is probably related the conspicuous and unique cellular phenomena which are so attractive to pathologists, forms the chief obstacle to all attempts to connect ætiologically the great variety of tumours of so many species of animals with one external agent or class of agent. The complete failure to provide a unifying conception of the disease has led cancer specialists to look upon the malignant transformation of a cell as a physiological reaction—or a perversion of a physiological reaction—to long-continued irritation. In other words, the disease is regarded as a particular problem in cell physiology, and however clearly external agents may be demonstrated as factors in the chain of causation of tumours their influence is considered to be entirely subsidiary to internal cellular capacities, and particularly to those which relate to cell division. In the final analysis of the pathology of tumours all this may turn out to be true, but as relatively little is known in this branch of physiology it is premature to indulge in speculation.

I have no desire in the present preliminary publication to discuss the very numerous theories, some of which are merely fantastic, which have been advanced to explain the origin of tumours. It is sufficient to draw attention to this conflict of opinion on the parasitic hypothesis. The work which I now report, and which has been carried on during the last two years, provides, I think, the reconciliation of the two views.

TECHNICAL NOTES.

1. *Filtration.*—An exaggerated importance has been attached to the filterability of a virus. This is reflected in the common use of the term "filterable virus" as a description of the whole class of very small organisms. The objections to the term come from two sides: first, the relatively gross spirochætes pass through bacterial filters readily, and cannot on any grounds be classed with the very small organisms which are invisible, or which, at least, cannot be resolved with the best microscopes in common use; and, secondly, for various reasons, some undoubted viruses are not filterable under the conditions in which they occur. The virus of vaccinia, for example, as it occurs in calf lymph is not filterable; also, the virus of herpetic encephalitis as it occurs in the brain tissue of rabbits is held back by filter candles. Filterability is determined by a number of factors, one of the most important being the properties of the fluid in which the virus is suspended. This is shown very easily with the Rous chicken sarcoma No. 1. If the disintegrated tumour be insufficiently diluted, or if the diluent employed be distilled water, the filtration is difficult and the filtrate is generally non-infective.

The best method of obtaining an infective filtrate is as follows. Healthy tumour tissue is selected and is minced with sharp scissors; the mince is then rubbed with sterile sand in a Wedgewood mortar in order to break up the cells. This is done very thoroughly. Saline or Ringer's fluid is then added to the mass in the proportion of 100 c.cm. to about 1 g. of tumour. After mixing thoroughly the muddy suspension is filtered under gravity through layers of paper pulp and sand, arranged in a long tube-filter, in order to remove sand and remnants of tissue. The filtrate thus obtained—the "sand filtrate"—is usually a faintly yellow transparent fluid, which passes, under moderate pressure, through a Chamberland L_2 or a Mandler candle with ease. The final "candle filtrate" when inoculated into a chicken in a dose of 1 c.cm. causes the formation of a tumour which is palpable in 14 days and almost always kills the chicken within 28 days. Rous showed that the addition of kieselguhr promotes the development of the new growth. In all the experiments described later a trace of silica has been added to the inocula.

2. *Media.*—In the course of this work a large variety of media has been prepared and tested. The formula of one only, that which has proved most satisfactory, will be given. The basis of the medium is Hartley's broth[5] to which is added 0·2 per cent. KCl. The broth is tubed in 5 c.cm. lots and is sterilised by steaming—never in the autoclave. To each tube of 5 c.cm. is added 1 c.cm. of fresh rabbit serum, after which the tubes are incubated at 37° C. for two days in order to test sterility. When sugars are required the sugar is added to the broth in bulk to give a concentration of 0·5 to 1 per cent.

3. *Aseptic Excision of Tumours.*—Bacteriological technique which involves the use of fresh animal tissue is complicated by the occurrence, especially after prolonged incubation, of contaminations. With chicken tumours the common contaminant is a white staphylococcus; with mouse tumours a Gram-negative bacillus; with rat material a Gram-negative bacillus sometimes occurs and about as often a streptococcus which under anaerobic conditions is very small, but which on solid media, incubated aerobically, assumes a larger size. When contaminations occur attempts to produce a tumour fail; in mice and in rats abscesses often follow the inoculation of material which is slightly infected.

When tubes have been incubated anaerobically it is not always immediately evident that a tube is contaminated; turbidity is not by any means constant. A state of affairs is attained which might be called "concealed contamination," the contamination being revealed only by means of subcultures, aerobic and *anaerobic*, in broth and on agar.

The following technique has been followed in order to reduce these contaminations to a minimum. The tumour-bearing animal is killed with chloroform or coal-gas and the carcass is then soaked in warm 2 per cent. lysol for five minutes. The subsequent procedures are carried out in a sterile room. The animal is pinned out on a sterile cork slab and the skin reflected so as to expose the tumour, the cutting of the skin and necessary dissection being performed by means of a cautery. After searing the surface, pieces of tumour are excised by means of a dry sterile knife and are dropped into tubes of medium. Unless such strict precautions are taken contaminations occur with disheartening regularity.

EXPERIMENTAL STUDY OF ROUS CHICKEN SARCOMA NO. 1.

It has already been remarked that the injection of 1 c.cm. of a Chamberland L_2 candle filtrate is followed by the formation of a tumour which appears in a fortnight and kills within a month. When the infectivity of such a filtrate is tested with doses of varying size it is shown that a proportionality between size of dose and time of appearance of tumour exists. This is well shown in the following protocol.

Experiment June 20th, 1923.—Chickens were inoculated with L_2 filtrate, all into the pectoral muscle, in quantities indicated in Chart 1. This experiment, modified in various ways, has been repeated over and over again and the result is constant with filtrates through close candles. The interpretation of the result is not possible without a count of the number of organisms per c.cm. in the infective fluid. Superficially it appears to support the view that the infective "agent" is a chemical substance, since proportionality, in such narrow limits, between dose and effect is not characteristic of living microbes.

INFECTIVITY OF "PRIMARY CULTURES."

A primary culture—a term of convenience—is obtained by placing a fragment of tumour in a tube of medium. The infectivity of the supernatant fluid is retained for a variable length of time depending upon the medium employed and the method of incubation. Retention of infectivity is favoured by anaerobiosis; the more completely oxygen is removed the longer the fluid remains infective. Similarly, the addition of rabbit serum to the broth helps to preserve infectivity. The findings may be summarised as follows:—

(1) When a piece of tumour—roughly 0·5 g. in weight—is dropped into 5 c.cm. of broth and the tube is incubated aerobically at 37° C., the supernatant fluid may remain infective in doses of 1 c.cm. for as long as two days. If the tube is incubated anaerobically the infectivity remains as long as four days, particularly if, before incubation, the air dissolved in the medium or "entangled" in the piece of tumour be removed by means of a Geryk pump.

(2) When the medium contains rabbit serum—5 c.cm. of KOI broth to which has been added 1 c.cm. of sterile serum—infectivity is retained after three days' incubation aerobically. If the aerobiosis be increased by using an Erlenmeyer flask instead of a test-tube infectivity is lost sooner. If a piece of tumour is placed in serum broth and the culture incubated anaerobically the supernatant fluid remains infective often for as long as seven days.

(3) When glucose, maltose, or lævulose are added to the medium an acid reaction occurs, the pH rising often as high as 4·0 to 4·5. With mannite, sucrose, galactose, lactose, dulcite, and salicin fermentation does not occur. The addition of a fermentable sugar tends to increase the time during which infectivity is retained, provided the acidity produced is not too great.

This summary of results of experiments with primary cultures is illustrated by the protocols below, but it must be noted that the size of the piece of tumour added to the medium is of primary importance. If a large mass of tumour—e.g., 2 g.—be added and the culture be incubated aerobically, then it is often possible to produce a tumour with the clear supernatant fluid after as long as seven days' incubation at 37° C. The general impression derived from a long experience of such cultures is that an "agent" diffuses from the tumour tissue and that it disappears slowly in the presence of rabbit serum and under anaerobic conditions, and more rapidly in the presence of oxygen and absence of serum. The larger the piece of tumour the greater the quantity of "agent" to diffuse, and consequently the longer the infectivity is retained.

Experiment Nov. 6th, 1923.—Chicken 44 was inoculated in the right pectoral muscle with 1 c.cm. of a culture made by adding a fragment of tumour (about 0·5 g.) to 5 c.cm. of glucose broth, the tube being incubated aerobically for three days at 30° C.; in the left breast with 1 c.cm. of an aerobic culture in rabbit serum glucose broth, incubated three days at 30° C. (Chart 2). Post mortem, there was no tumour in the right breast; in the left a large tumour.

This experiment shows that serum tends to preserve infectivity.

Experiment Dec. 27th, 1923.—Two sterile Erlenmeyer flasks were taken; into each 5 c.cm. of rabbit serum glucose broth were placed. A piece of tumour tissue was now placed in the medium in each flask. One flask was incubated aerobically for three days at 30° C., the flask being covered with a rubber cap to prevent evaporation; the second flask was incubated anaerobically for three days at 30° C. Chicken 47 was then inoculated in the right breast with 1 c.cm. of the aerobic culture and in the left breast with the anaerobic culture (Chart 3). Post mortem, there was no tumour in the right breast; in the left a large tumour.

DESTRUCTION OF THE AGENT WITH CHLOROFORM.

Rous[4] showed that carbolic acid, toluene, and chloroform all destroy the agent in a relatively short space of time. I have confirmed all his statements, but here I wish particularly to describe the method of rendering "sand filtrate"—which will produce a tumour in doses of 0·05 c.cm.—innocuous by treatment with chloroform.

Healthy tumour tissue is taken and is disintegrated with sand. The mass is then mixed with Ringer's fluid, the volume of fluid used being 100 c.cm. to about 5 g. of tumour. The mixture is filtered through well-packed paper pulp and sand and the filtrate should be quite transparent. Ten c.cm. of the clear sand filtrate is placed in a boiling tube by means of a pipette. The fluid is delivered neatly to the bottom of the tube without wetting the sides. A few drops of chloroform are then run down the sides of the tube, which is held in a slanting position. In this way, although some of the chloroform sinks to the bottom of the tube to form globules, a portion remains for a time as a thin film on the surface. The tube is then placed in a beaker of water, the temperature of which is 37° C., and is kept in the incubator. After half an hour has elapsed the chloroform globules are taken up in a Pasteur pipette and mixed repeatedly with the bulk of the filtrate. The object of this manœuvre is to facilitate the saturation of the fluid with chloroform. The tube is again incubated in water kept at 37° C., and is left until three hours' incubation has been completed. The chloroform is then removed completely by means of a Geryk pump. "Sand filtrate" which has been treated in the above fashion now fails to infect in doses of 2 c.cm., whereas a control tube treated similarly, but with saline instead of chloroform, is still infective in doses of 0·2 to 0·25 c.cm.

The following experiment shows the importance of temperature and of complete saturation of the filtrate with chloroform in the destruction of the virus.

Experiment Dec. 12th, 1923.—Chicken 49 was inoculated with 1 c.cm. sand filtrate which had been saturated with chloroform and kept at a temperature of 37° C.; Chicken 50 with 1 c.cm. of the same filtrate which had been saturated with chloroform and kept at room temperature; Chicken 51 with 1 c.cm. of the same filtrate incompletely saturated with chloroform and kept at 37° C. for three hours (Chart 4).

CHART 4.

50	—	—	•	▨	† 35TH DAY.
51	—	—	•	▨	† 38TH DAY.

For the rapid destruction of the virus the filtrate must be saturated with chloroform and the temperature be kept in the neighbourhood of 37° C. It is to be noted that it is insufficient merely to place the tube in the incubator and expect the contents to attain the temperature in a short time; the tube must be placed in water at the required temperature.

EXPERIMENTS TO SHOW THAT TWO FACTORS EXIST IN INFECTIVE FLUID.

Experiments have already been described in which it is shown that "primary cultures" in broth and in rabbit serum broth become non-infective in two to seven days, the time depending upon the amount of tumour tissue, the composition of the medium, and the conditions of incubation. From the beginning of this work on the Rous sarcoma I suspected that this loss of infectivity does not depend upon the death of a virus, but upon the disappearance of an accessory chemical factor which governs infection of cells. The following experiment shows that this is true. The accessory factor, a product of tumour cells, is obtained by killing the virus in a "sand filtrate" with chloroform in the manner already described. The suspension of the virus consists of a non-infective primary culture.

Experiment Jan. 14th, 1924.—A culture was made by placing a fragment of healthy tumour tissue in 5 c.cm. of rabbit serum glucose broth, contained in a small Erlenmeyer flask, and incubating aerobically at 37° C. for three days. Clear "sand filtrate" was treated with chloroform in the manner already described and the chloroform removed completely under the pump. Chickens were now inoculated as shown in Chart 5.

67	1 cc TREATED FILTRATE.	—	—	—	—	—	—
68	0·5 cc CULTURE +0·5 cc FILTRATE	—	—	○	▨	◯	† 38TH DAY.

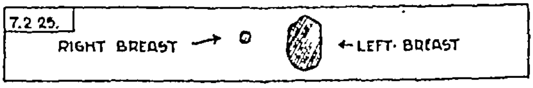
It is clear from this experiment, one of many, that a tumour extract—the "sand filtrate"—treated with chloroform and thereby rendered innocuous has a property which, when aided by a property of an inert primary culture, can bring about the formation of a neoplasm. The interpretation of these results, which were first obtained in a rather different form in November, 1923, is as follows. The chloroform-treated "sand filtrate" contains a labile chemical substance which in some way, as yet unknown, renders the cells susceptible to infection by the virus contained in the primary culture. The proof that this is an accurate conception of the process will be made clear later. The existence of two factors in primary cultures can be shown by means of the centrifuge.

SPINNING EXPERIMENTS.

The interpretation of the results obtained with infective fluids which are spun at high speed depends in a large measure, but not entirely, upon the fact that a proportionality exists between size of dose and effect. This is illustrated by the following experiment.

A "primary culture" in rabbit serum glucose broth, incubated at 39° C. anaerobically in a McIntosh and Fildes tin for five days, was taken and the clear supernatant fluid pipetted off without disturbing the tumour tissue at the bottom of the tube. The acidity of the fluid was between pH 5·0 and 5·5. The fluid was spun in a conical tube for two hours at a speed of 9000 revolutions per minute. Rather more than 1 c.cm. of the top layer of the spun culture was then taken off with a Pasteur pipette, the greatest care being taken to avoid disturbing the small amount of deposit at the bottom of the tube. Next, 1 c.cm. was taken from the lowest layers, the deposit being included. A chicken was then inoculated in the right breast with 1 c.cm. of the fluid from the top layer, and in the left breast with 1 c.cm. from the lowest layer. The chicken died in 20 days and when examined post mortem the tumours in the breasts were relatively as indicated in the chart here given (Chart 6).

CHART 6



Such an experiment has been taken to indicate a "shift" of the particulate agents, whether purely under centrifugal force or whether as part of a general shift of large colloid protein masses which form in medium containing tissue. In an ordinary infective disease, the clinical signs of which are elevation of temperature, appearance of a rash or vesicles, and so on, a delay in the appearance of signs would be more difficult to interpret. But with a tumour which always occurs locally at the site of injection and which manifests itself as a swelling, the hazards are less.

With candle filtrates and with five-day cultures in media which do not contain fermentable sugars—i.e., when the pH is 7·8 to 7·9—the shift of virus is so small as to be open to doubt. The effect of acidity in aiding spinning is thus very great; all attempts to spin out the virus completely, even with acid cultures, in this way have failed. An additional advantage is obtained by lining the centrifuge tubes with a thin film of nutrient agar. The agar becomes detached during spinning and, when the machine is stopped, it is found at the bottom of the tube. The exact part which agar plays has not been determined, but it was first employed to provide a material upon which it was imagined the virus would stick firmly. This, however, may be passed over for the present; the fact is that by using agar films acid infective fluid can, by a short period of spinning, be rendered inert in doses double and often treble the usual infective dose, as the following experiment indicates.

Experiment Feb. 7th, 1925.—A portion of a five-day culture of a tumour in rabbit serum maltose broth was spun for 35 minutes in a tube lined with agar. The pH of the culture had increased from 7·8 to 5·0 during incubation. After spinning, Chicken 144 was inoculated in the right breast with 1 c.cm. of the supernatant fluid; in the left breast with 0·5 c.cm. of the portion of the culture which had not been spun. Chart 7 shows the result. Post mortem, there was no tumour in the right breast.

When the deposit which is obtained by spinning a five-day anaerobic primary culture in rabbit serum glucose broth is washed twice with saline, it is found that the final emulsion of deposit is inert. This might readily be supposed to be because the virus has been washed away. It is not so, however, as can be proved by inoculating a chicken with a mixture of washed deposit and innocuous supernatant fluid, when a tumour forms in the usual time. This is well shown by the following experiment:—

Experiment Sept. 2nd, 1924.—Five-day anaerobic cultures in rabbit serum glucose broth were taken and spun in four conical centrifuge tubes, two of which were lined with agar and two were not. The first spinning was for 40 minutes at 9000 revolutions; the topmost layers were pipetted off from the two agar-lined tubes—in all 4 c.cm. were taken—and put aside. The fluid in the two remaining tubes was pipetted off with care, leaving only the small amount of deposit which had formed. The deposit in each tube was mixed thoroughly with 5 c.cm. of saline and the two tubes again spun at 9000 r.p.m. for 40 minutes. Again the fluid was removed and the deposit mixed with saline and the mixture spun. In this way the deposit was washed twice. It was finally emulsified in 1 c.cm. of Ringer's fluid and the following experiment performed.

Chicken 150 was inoculated with 2 c.cm. of the fluid taken from the agar-lined tubes; Chicken 151 with 0·6 c.cm. of washed deposit plus 0·8 c.cm. Ringer; Chicken 152 with 1 c.cm. of fluid from the agar-lined tubes to which was added 0·4 c.cm. of washed deposit. Chart 8 shows the result of the experiment.

CHART 8.

Chickens 150 and 151 were killed on Oct. 31st, 1925—the fifty-fourth day—and there were no signs of a tumour.

It is not easy to obtain such a perfectly clean result. A more frequent result is indicated in the next experiment.

Experiment Dec. 13th, 1924.—Spinning and washing were carried out as before. Chicken 15 received 1·5 c.cm. of supernatant fluid from agar-lined tubes; Chicken 16 received 0·5 c.cm. of washed deposit plus 0·5 c.cm. Ringer; and Chicken 17 received a mixture of 0·75 c.cm. supernatant fluid and 0·25 c.cm. washed deposit. The result was as shown in Chart 9.

17	0·75 cc SAND FILTRATE + 0·25 cc WASHED DEPOSIT.	•	●	● † 25TH DAY.

Chicken 15 eventually died on Feb. 2nd, 1925, 51 days after being inoculated; Chicken 16 was killed three months later and there was no sign of a tumour.

These experiments have been carried out 15 times; in two instances the cultures proved to be non-infective—in each case there was a "concealed contamination"; in two experiments tumours have developed in the chicken inoculated with washed virus, once after 30 days and once after 28 days. The remainder of the experiments are fairly represented by the protocols given.

When candle filtrates of a tumour are taken, made acid with NaH_2PO_4, and spun in the same way the results obtained are of the same kind, but it is more difficult to render the fluid in the agar-lined tubes non-infective.

Experiment Nov. 11th, 1924.—A tumour filtrate (Mandler candle) was acidified with NaH_2PO_4, the pH being brought to 5·5. The acidified filtrate was then spun, the deposit in the two tubes being washed, as in the protocols already given (Chart 10). Post mortem, it was found that the tumour in Chicken 184 had penetrated the peritoneal cavity into which hæmorrhage had occurred, causing death. The tumour in Chicken 185 was confined to the pectoral region and was much larger than that in Chicken 184.

	LEFT BREAST: 1 cc SUPERNATANT FLUID + 0·3 cc WASHED VIRUS.	—	•	●	● † 21ST DAY.

It will be noted that my practice has been to give double doses of supernatant fluid and washed virus when these are inoculated separately. This, of course, is the recognised safe method of control. If, however, the first and third chickens of an experiment be inoculated with the same volume—usually 0·75 c.cm.—of supernatant fluid diluted with Ringer's fluid for the first chicken and washed virus for the third; then the results are similar to those shown in the first protocol (Experiment Sept. 2nd, 1924).

The experiments show that both in primary cultures and in candle-filtrates of the tumour there are two factors which are necessary to the production of a tumour; the one is particulate and is therefore probably a virus; the other, being uninfluenced by spinning, is probably a chemical substance. Neither of these factors operating alone will cause the formation of a sarcoma.

The bearing which these findings have upon the pathology of the Rous tumour and, as will be shown, upon tumours generally, is most important. To return to the central difficulty of tumour ætiology, specificity. It seems to me obvious that, since the virus alone is not infective, the specificity of the Rous tumour must be carried by the second—the chemical—factor derived from cells. (That it is not a toxin or other product of culture is evident from the results of spinning candle filtrates of tumours and from the fact—shown later—that subcultures alone are not infective.) It is very probable that the virus of the Rous tumours VII. and VIII. is the same as that of No. 1†; the chemical factor in each case would, I presume, be different. In this way the specificity is again related to the cells, but in the case of the filterable tumours, to a cell derivative which can be separated from the cells. I propose to call this chemical substance the "specific factor."

At this point it is convenient to refer to attempts to stain and see the virus. Most of the stains recommended for the study of small organisms have been employed in this research. Giemsa's fluid in particular has been thoroughly tried. In order to obviate repetition in the later parts of this paper it is as well to state at the outset that all attempts to stain and see the virus, using for the purpose a 2 mm. apochromatic lens with eye-pieces ranging from 6 to 20, have failed. The "granules" which can be stained in films made from a medium containing tissue have been seen but that they are not the virus is shown by the following observation. A film was made from a five-day primary culture of the Rous tumour in rabbit serum glucose broth; a chicken was then inoculated with 1 c.cm. of the culture. Next the culture was spun at 9000 revolutions per minute for

---

† This cannot now be tested as the tumours VII. and VIII. have been lost. Dr. Rous very courteously sent me dried powder of the tumours, but they proved to be inert.

40 minutes in an agar-lined tube. The upper part of the fluid was removed with a pipette and a film made; 1 c.cm. of the fluid was then injected into a chicken which did not develop a tumour; the chicken inoculated with the unspun fluid died of a large tumour three weeks later. The films were passed through fixative together and then stained together with Giemsa's long method; both showed innumerable pink granules on the border-line of resolution. Such experiences as these have led me to the opinion that such granules are not the virus. The visual discovery of such small organisms is obviously a special problem in optics. Fortunately, my colleague, Mr. J. E. Barnard, F.R.S., has undertaken this work. His report upon it follows this paper.

THE CULTIVATION OF THE VIRUS IN VITRO.

Whilst the results of spinning experiments show that one factor in the tumour-producing filtrate is particulate and is therefore probably a virus, the proof of multiplication in vitro is essential for the final justification of this conclusion. To describe completely the attempts, successful and unsuccessful, to cultivate the virus would expand this paper unreasonably; details will be left to the technical journals. Here it is sufficient to say that the most useful medium employed is that which has been described already. To 6 c.cm. of rabbit serum KCl broth a fragment of chick embryo is added. The age of the embryo used has generally been 12–16 days. The tube is then inoculated with a loopful of primary culture and is now called the first subculture. It is incubated in an anaerobic tin at 35°–36° C. for four days, when the second subculture is made into similar medium containing freshly removed embryo. The maximum growth as judged by the results of experiments on chickens is obtained on the fourth to fifth day of incubation.

The dilution with each subculture is at least a thousand times; in a fifth subculture, therefore, the original inoculum has been diluted 10^{15}, or a thousand billion times. If tumours are produced with subcultures beyond the fifth we may be certain that growth has taken place. The following protocols show results obtained with such subcultures.

Experiment Sept. 18th, 1924.—Chicken 157 was inoculated with 1 c.cm. of sand filtrate which had been treated with chloroform; Chicken 158 with 1 c.cm. of a fifth subculture of the tumour virus; Chicken 159 with 0·5 c.cm. of the sand filtrate plus 0·5 c.cm. of the fifth subculture. The results are seen from Chart 11.

Experiment Dec. 4th, 1924.—On Dec. 2nd, 1924, fragments of tumour were placed in tubes of glucose broth and the tubes incubated anaerobically in a McIntosh and Fildes tin for two days at 39° C. On Dec. 4th supernatant fluid was taken from the tubes without disturbing the tumour tissue. The fluid was spun in agar-lined tubes for an hour and three quarters at 9000 revolutions, and the supernatant fluid pipetted off. Chickens were then inoculated as shown in Chart 12.

MAMMALIAN TUMOURS.

Four standard tumours of rats and mice have been studied. These are: (1) A spindle-celled sarcoma of the mouse, strain 37/S of the Imperial Cancer Research Fund; (2) the Jensen rat sarcoma; (3) a carcinoma of the mouse, strain 63; and (4) a rat carcinoma, strain 9, both of the Imperial Cancer Research Fund. The mouse tumours 37/S and 63 give 100 per cent. of takes in mice, metastasise, and always kill the host. The rat tumours often retrogress. All four tumours are accepted as genuine neoplasms by competent pathologists in this country and abroad.

The first part of the investigation was a re-examination of the filterability of the sarcomata. In this work, during the early months of 1924, I enjoyed the assistance of my colleague Dr. W. J. Purdy. The mouse tumour 37/S, especially, was thoroughly tested. The method of preparing extracts was similar to that described for the chicken tumour. The candle used was a Chamberland L_1, which permits *B. prodigiosus* to pass when a rich broth culture is filtered; cells, however, are invariably kept back. In different experiments the tumour tissue was ground with sand at freezing-point, at room temperature, and at 37° C. The diluent was varied from time to time; the pH was varied from extreme acidity to extreme alkalinity. But under no conditions were we able to produce a tumour with a cell-free filtrate. It may be taken as certain that the mouse sarcoma 37/S is not a filterable tumour in the sense that the Rous chicken sarcoma is. The same may be said of the Jensen rat sarcoma, though fewer experiments were made with this tumour. The carcinomata were not reinvestigated.

Mouse Sarcoma 37/S.

The survival of the tumour cells in vitro was first tested. This was repetition of unpublished work which I had first carried out in 1918–19 whilst on the staff of the Imperial Cancer Research Fund. The general result of these studies is that the tumour cells die relatively rapidly when incubated at 37° C. in Ringer's fluid or broth. This is illustrated by a typical experiment.

Several tumours were excised aseptically and minced with sharp scissors; 1 c.cm. of the mince was then delivered by means of a syringe into 5 c.cm. of Ringer contained in a test-tube. Another portion of the mince, contained in a sterile capsule, was kept in the cold. The tube of Ringer containing tumour cells was now placed in a beaker of water the temperature of which was 37° C. and kept at this temperature for 18 hours. Two series of 12 mice were now inoculated, one with the incubated tumour cells which had been separated from the Ringer by spinning; the second set with the tumour emulsion which had been kept in a sterile capsule in the cold. The second set of mice developed tumours in the usual way, whilst those injected with incubated cells remained exempt and were eventually killed.

The explanation of the early death of cells is certainly not simple. The addition of serum tends to preserve the viability of cells, as does also an abundant supply of oxygen. Absence of oxygen—for incubation in Ringer is partial anaerobiosis—plays an important part in the lethal process. When a piece—about a gramme—of healthy tumour is dropped into a tube of rabbit serum KCl broth and the tube is incubated 24 hours in an anaerobic tin and the clear supernatant fluid then injected into mice, about 50 per cent. of the animals develop tumours which appear usually on the fourteenth to eighteenth day and attain a large size—2–3 g.—in four to five weeks. The tumours thus produced have the structure characteristic of 37/S, and behave identically when transplanted in other mice. Are they produced by inoculation of an occasional cell which survives anaerobic incubation? Or are they genuine new growths produced by infecting the host's own cells with a virus derived from the incubated tumour tissue? It is probable from what has already been said that the second explanation of their origin is the correct one. The following experiments prove this.

A number of healthy tumours were removed and placed—about 2 g. per tube—in tubes of rabbit serum KCl broth. The tubes were now put into a McIntosh and Fildes anaerobic jar which was evacuated with a Geryk pump. As the pressure in the jar fell gases bubbled out of the tubes and especially from the surface of the tumour tissue. Pumping was continued till no more gas was given off. Hydrogen was then run into the jar and the coil of platinised asbestos warmed with an electric current in order to achieve complete anaerobiosis. The jar was incubated at 37° C. for three hours and was then again evacuated. This time the medium in the tubes, being warm, boiled under the reduced pressure. In this way the air entangled on the tumour was completely removed. The jar was made anaerobic and then incubated for 24 hours at 37° C. The jar was now opened, the fluid in the tubes pipetted off, spun in the centrifuge, and the topmost layers of fluid taken off and inoculated into mice. The mice had well-developed tumours in 14 days, which were removed in 21 days and the experiment repeated with them. The same result was again obtained. Thus by incubating under perfectly anaerobic conditions the percentage of tumours obtained *may* reach 100. The following is the protocol and chart of the second experiment.

Experiment April 30th, 1925.—About 1 g. of healthy tumour tissue was placed in a tube of rabbit serum KCl broth; incubated 26 hours anaerobically in a jar. On May 1st four mice were inoculated, each with 1 c.cm. of supernatant fluid (Chart 14). Lest doubt remain that cells have survived anaerobic incubation and originated tumours, the following experiment was performed.

Experiment May 22nd, 1925.—Cultures were made as before by adding healthy tumour tissue to medium and incubating 24 hours at 35° C. The cultures were now mixed in a boiling tube and one half inoculated into mice (A); the liquid remaining was filtered through a Chamberland L₁ candle. Chart 15 shows the result of the experiment. Primary cultures of 37/S, incubated for three days in this way fail to produce tumours. Proof that this is not due to death of the virus will be given in another paper. Charts 14 and 15 are the best results obtained. When dry necrotic tumours are used the results of inoculation may be quite negative.

It is now certain that a typical mammalian sarcoma (37/S) can be transferred with a cell-free filtrate, under the special conditions described. The Rous chicken tumour is thus, in reality, not exceptional; it differs from the mammalian sarcoma 37/S merely in the fact that its accessory chemical factor is either more abundant or more stable. All the evidence points to the oxygen lability of the chemical factor and it is possible that the explanation of the uniform failure to transfer 37/S with tumour filtrates is due partly to the oxidation of the specific factor in grinding with sand, and partly to the excessive dilution necessary to form a filterable mixture.

Jensen's Rat Sarcoma, Rat Carcinoma 9, and Mouse Carcinoma 63.

It will be observed that proof of the existence of an extrinsic cause of 37/S sarcoma proved to be a lengthy and laborious research. For the remaining three tumours an indirect method has been adopted to obtain the same information. The method consists in substituting the virus of one of these tumours for that of the Rous sarcoma in the manner indicated in the following experiments:—

Experiment April 17th, 1925.—Sand filtrate of Rous chicken sarcoma was prepared from healthy tumour tissue. The filtrate was perfectly clear, faint yellow in colour, and viscid. 10 c.cm. were saturated with chloroform and then incubated in a beaker of water kept at 30° C. The chloroform was completely removed by means of a Geryk pump and the following experiment was made:—

Chicken 251 was inoculated with 1 c.cm. of the filtrate; Chicken 252 with 0·5 c.cm. of the filtrate to which was added 0·5 c.cm. of a culture made by adding a fragment of 63 carcinoma to rabbit serum KCl broth and incubating anaerobically for three days at a temperature of 30° C.; and Chicken 253 was inoculated with 1 c.cm. of the culture of 63 carcinoma. The result is shown in Chart 16.

It is evident from this experiment, which has been repeated many times, that the culture of 63 carcinoma can replace the virus of the tumour. The tumours thus produced distinguished histologically or biologically Rous tumour.

The next protocol is included to show is the preparation of the specific

Experiment May 9th, 1925.—Clear sand filtrate was prepared from a Rous tumour and two lots, each of 10 c.cm., were taken. To one a few drops of chloroform, insufficient to saturate the mass, were added and the mixture incubated for three hours; to the second lot of 10 c.cm. rather more than 1 c.cm. of chloroform was added and saturation facilitated by repeated mixing. The second tube was incubated for 5 hours. Chickens were inoculated as follows:—

(*a*) Chicken 284 was injected with 1 c.cm. sand filtrate insufficiently treated with chloroform; Chicken 285 with 0·5 c.cm. to which was added 0·5 c.cm. of a three-day primary culture of carcinoma 63; and finally, Chicken 286 was inoculated with 0·5 c.cm. of filtrate diluted to 1 c.cm. with 0·5 c.cm. saline. The result is indicated on Chart 17.

289	0·5 cc FILTRATE + 0·5 cc CULTURE OF RAT CARCINOMA 9.	—	—	—

Rat Carcinoma 9 and Jensen's Rat Sarcoma.

These tumours will be taken together in order to save space. Cultures of them are made in the usual manner by adding a fragment of healthy tumour to a tube of rabbit serum KCl broth. Carcinoma 9 usually becomes very hæmorrhagic and a young tumour must therefore be taken. In the case of the Jensen rat sarcoma retrogression is so common that it is advisable to chart the tumour frequently in order to be certain that it is taken in the growing phase. Such cultures may now be substituted for the Rous cultures, as in the experiments already taken from protocols for tumour 63.

Experiment May 15th, 1925.—10 c.cm. of water-clear sand filtrate of a Rous tumour was taken and treated with chloroform. The following chickens were inoculated: Chicken 291 with 1·5 c.cm. treated sand filtrate (specific factor), Chicken 292 with 0·5 c.cm. filtrate plus 0·5 c.cm. saline, Chicken 293 with 0·5 c.cm. filtrate plus 0·5 c.cm. of a twelfth subculture of the Rous tumour, Chicken 294 with 0·5 c.cm. filtrate plus 0·5 c.cm. of a culture of rat carcinoma 9, and Chicken 295 with 0·5 c.cm. filtrate plus 0·5 c.cm. of a culture of the Jensen rat sarcoma (Chart 19).

Again, the tumours produced with the specific factor of the chicken sarcoma, together with cultures from the rat tumours, do not differ in structure from the ordinary Rous No. 1.

It has now been shown that the non-specific factor can be obtained from three mammalian tumours. Experiments with subcultures of these tumours are not yet complete, but there is no reason to doubt that the element provided is a virus.

HUMAN TUMOURS.

Tests with three tumours only have been completed. One of these, for which I am indebted to Dr. A. G. L. Reade, was a scirrhous carcinoma of the breast. Cultures were made, but proved to be contaminated. Nevertheless, chickens were inoculated with the culture and specific factor but results were negative. The second was a sarcoma of the thigh, pieces of which were kindly given to me by Sir Cuthbert Wallace. The cultures which were made from this tumour were uncontaminated, but experiments on chickens failed completely. The third was an adeno-carcinoma of the breast; I am indebted to Prof. G. E. Gask for the opportunity to test it. Cultures were made both from the tumour itself and from an axillary gland which was enormously enlarged. There was no contamination in the cultures. The experiment was made on May 23rd, 1925. Chart 20 shows the result.

Chick 297 died on the twenty-third day; and Chick 298 on the twenty-eighth day.

The tumours produced were again indistinguishable from the Rous tumour.

One human tumour then behaves like the rat and mouse tumours. The negative result with the human sarcoma may mean that a group of viruses—not interchangeable—exist which cause tumours, but obviously more experiments must be done before an opinion can be formed. The failure with the scirrhous tumour can be ignored owing to the contamination of the culture.

DISCUSSION.

It has now been shown that the Rous tumour No. 1 is caused by a virus which has been cultivated; that the mouse sarcoma 37/S can be transmitted with cell-free filtrate; that the rat tumours 9 and J.R.S. and the mouse carcinoma 63 and a human breast carcinoma all provide a factor which can replace the virus of the Rous tumour in the genesis of a chicken sarcoma.

The common factor of the last four tumours is almost certainly a virus. The production of tumours with remote subcultures remains to be done. Further, it has now been shown that the virus alone is unable to bring about the malignant transformation of a cell. An adjuvant, fortunately provided in abundance by the chicken sarcoma, is necessary; this adjuvant

I have called the specific factor. Superficially, it might be thought that Ball's term "aggressin" would appear satisfactory, but a casual analysis of the facts relating to an aggressin shows that this is not so. As an example of an aggressin the toxin of *B. welchii* will be taken. The toxin is separated from the bacilli by filtration and the minimal lethal dose for mice determined. Bacilli, conveniently grown on solid medium are washed free of toxin, and are then found to be perfectly harmless to mice. If, now, mice are inoculated with a sublethal dose of toxin to which has been added washed *B. welchii*, an infection is set up, more toxin is produced in vivo, and the mouse eventually dies of a spreading gangrene with toxæmia. When the bacilli added to the toxin are *B. welchii* the infection produced is characteristic of *B. welchii* infections; when *Vibrion septique* is added the disease produced is characteristic of *Vibrion septique*;[7] and similarly, toxin-free harmless tetanus spores mixed with sublethal doses of *B. welchii* toxin produce tetanus.[8] Thus, the specificity in these cases depends upon the microbes; the aggressin, acting equally well for all three, produces a microscopic lesion which in some way, not yet fully understood, enables these anaerobic organisms, which alone are harmless saprophytes, to proliferate in the tissues and there to make their characteristic poisons. These facts have been established by experiments similar to, but much easier to perform than, those which have been employed in the work described in this paper. The differences between an aggressin and the specific factor of a tumour are evident.

These researches have led me to look upon cancer—using the term in its widest sense—as a specific disease caused by a virus (or group of viruses). Under experimental conditions the virus alone is ineffective; a second specific factor, obtained from tumour extracts, ruptures the cell defences and enables the virus to infect. Under natural conditions continued "irritation" of tissues sets up a state under which infection can occur. The connexion between the specific factor of a tumour and an irritant remains to be investigated. Some of the relatively unimportant "irritants" are known, such as coal-tar, paraffin oils, &c. The virus probably lives and multiplies in the cell and provokes the cell to continued multiplication.

The methods of experiment now described, and the obvious extensions of them, give the means of classifying the viruses, of investigating the nature of the specific factor, and of testing suspected "irritants," such as preservatives in foods, which may play a rôle in the genesis of a tumour.

I am indebted to the Executive Committee of the Imperial Cancer Research Fund for placing at my disposal their unrivalled series of animal tumours. My thanks are due to my former chief, Dr. J. A. Murray, F.R.S., for his continued critical interest in the work. To my colleague, Dr. W. J. Purdy, I am indebted for assistance in many experiments, for help in the routine inoculation of tumours, and for the preparation of charts; over and above this direct help, I desire to acknowledge the advantages I have derived from his criticisms both of experiments and the interpretations placed upon results. Finally, I wish to state that I owe much to my laboratory servant, Mr. W. Hall, for his willing service.

THE MICROSCOPICAL EXAMINATION OF FILTERABLE VIRUSES

ASSOCIATED WITH MALIGNANT NEW GROWTHS.

BY J. E. BARNARD, F.R.S.

(*From the National Institute for Medical Research, Hampstead, N.W.*)

(*With Illustrative Plates.*)

Introduction.

THE search for filterable viruses by microscopical methods presents problems of great difficulty, due for the most part to the optical limitations of the microscope. The evidence that such organisms exist is based upon numerous experiments in which infective material has retained its infectivity after passing through a filter that will not pass the smallest known visible organism. There is at present no method in general use by which such filters can be standardised, and it is therefore not certain that filterable viruses can be regarded as organisms of any definite order of size. Other factors than size of the organism influence the result of filtration experiments, not the least being variability of the filters themselves and the viscosity of the filterable material. If filtration did give more exact information as to the size of any given organism it would then perhaps be advisable to adopt some other standard of reference than permeability. Such a standard might be the limits of microscopical resolution, by which all bodies of less than 0·25 μ in their greatest diameter should be regarded as filter-passers, although in that case some other more suitable name might well be found.

It is necessary to consider the main factors limiting both visibility and resolution in the microscope as these limits operate so definitely in any attempts to see or to photograph small bodies. It is also of interest to realise the probable size of filterable viruses in relation to the smallest micro-organism on one hand, and a large molecule on the other. The latter limits are shown diagrammatically in Figs. 1 and 2. The inner circle A in Fig. 1 may be regarded as a hæmoglobin molecule, molecular weight 16,000 approximately. The circles B, C, D, represent the orders of microscopical resolution obtainable if certain ultra-violet radiations are used of wave-lengths 232 μμ, 257 μμ, and 275 μμ respectively; they do not indicate the magnitude of relative wave-lengths. The circle E represents the relative position of the green line in mercury wave-length 546 μμ, with which the visual observations have been made. Between the positions A and B, therefore, no method at present exists by which microscopical resolution can be obtained. (The millimicron μμ = one-thousandth of a micron, 10^{-7} cm.) It is convenient to use the micron for microscopic dimensions and the millimicron for wave-length estimations. To enable a comparison to be made with an organism of known size, reference must be made to Fig. 2, which is on one-tenth the scale of Fig. 1. In this the relative wave-lengths are represented by the small inner circles B, C, D, and E, and the outer circle F represents a body of 1·0 μ in diameter, the average size of a small micrococcus. On reference again to Fig. 1 it will be seen that to obtain the necessary microscopical resolution, a term which will be explained later, and which is proportional to the wave frequency of the light used, it is necessary to use light of wave-length 275 μμ if a body of 0·1 μ in diameter is to be represented, whereas wave-length 257 μμ would resolve down to approximately 0·075 μ, a dimension that is of importance in the present investigation. Fig. 2 gives some idea of the possible sizes of filter-passers. It is certain that they are made up of a considerable number of complex molecules, but no exact limit is assignable in either direction. There are, however, two physical considerations that do suggest a limit of smallness. One is the difficulty there would be for a small body to overcome its relatively great surface tension and to divide and reproduce itself by binary fission as larger organisms do; the other is the mean free path, or Brownian motion, which it would acquire if it exists as a separate particle. There are reasons to think that these conditions are provided against in the life processes of small organisms, and the evidence that this is so will be detailed later; at the same time these factors must and do operate at times, and they may therefore be regarded as limiting factors in any estimation of size. There are other circumstances that cannot be detailed here suggesting that filterable viruses are of sizes represented by the distance between B and D, and can therefore be photographed by ultra-violet light of the wave-lengths indicated. No objective has yet been constructed which works to or near the theoretical limit that the shortest of these wave-lengths should give, but experimental efforts indicate that such will be evolved in due course.

Fig. 1.

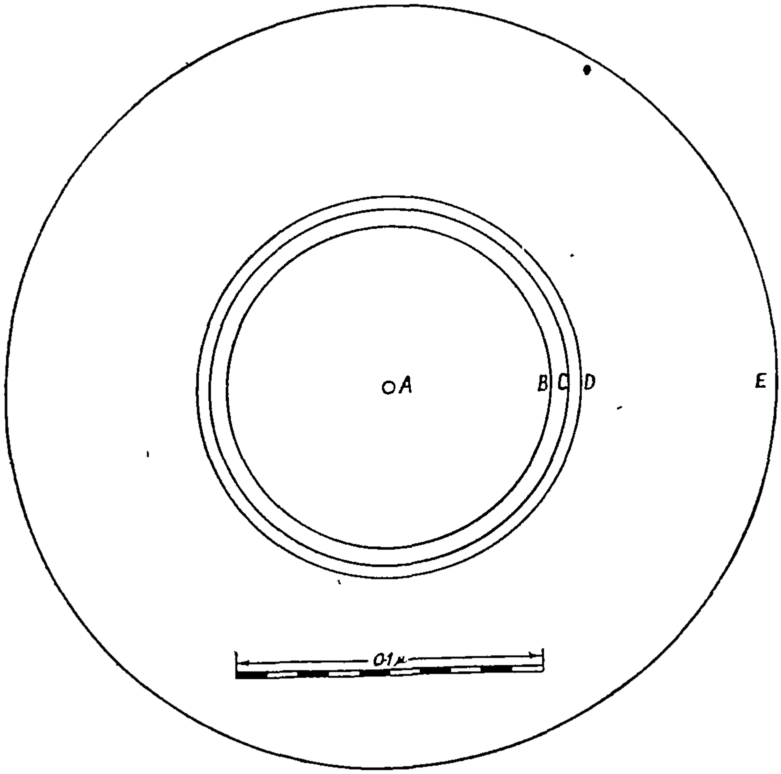

Fig. 2.

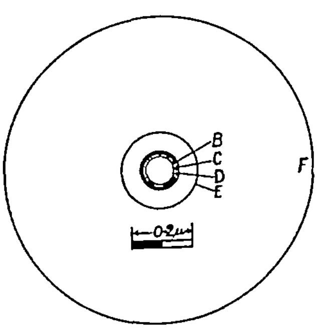

Diagrams to show relative magnitudes.

The Microscopical Limits of Observation.

Microscopic objects may be divided into two classes, those that are seen by transmitted light and those that can be made self-luminous. The former are seen as the result of partial or of selective light absorption, that is, they may be semi-opaque, the elements of structure absorbing more or less light, or they may be seen in colour as the result of selective absorption as in a stained preparation. For an object to be self-luminous, it must be illuminated in such a manner that no direct light reaches the micro-objective but only that which is refracted, diffracted, or scattered by the object itself. Under these conditions an object is seen as a bright image on a dark background and the method is known as dark-ground illumination. The main purpose in all microscopical observations is to obtain the greatest resolution, and the term, "limits of resolution," is applied to that state of affairs in which no further separation of elements of structure is obtainable. Only late in the last century was it definitely recognised that there are theoretical limits beyond which the microscope as ordinarily employed cannot go, and these theoretical limits are now all but reached under proper conditions of use. If two points in an object are within a certain limiting distance of one another they cannot be separated by any known means. Further, if an isolated element of structure is smaller than a certain limit the image seen does not represent its exact form or size. Magnification as such does not help, as, however much the image may be enlarged, there is no resulting increase of resolution. The main factors governing resolution are the numerical aperture of the objective used and the wave-length of the light employed. The best results are therefore to be expected when numerical aperture (N.A.) is large and the light used of the shortest wave-length practicable. While this power of delineating fine detail is of primary importance in all observation, another factor comes in with self-luminous objects which is hardly less important, and that is visibility. The term "ultra-microscope" is often inaccurately applied to all illuminating appliances that render an object self-luminous, but it should in fact only be used to describe apparatus which renders particles visible that are smaller in all dimensions than the resolution limits. In actual practice this limit is reached with isolated objects or elements of structure that are less than 0·25 micron in diameter. When objects larger in any dimension than this limit are being so observed the method may be described as "dark-ground" illumination, whereas, when the objects are smaller, "ultra-microscopy" is the correct term. Neither dark-ground illumination nor the ultra-microscope can be regarded as a means of increasing resolution, their main purpose being to obtain greater visibility, although the full resolving power of any given lens may be secured by this means. In the light of recent experiments it is, in fact, clear that full resolving power is obtained more certainly by an efficient dark-ground illumination method than by any other means. In theory there is no limit to the smallness of an object that can be made visible if a sufficiently powerful illuminant is used. In practice, however, the dark-ground illumination limits are governed by the following conditions:—

(1) That the particles under observation can themselves scatter enough light to enable them to be seen.

(2) That the particles are separated from one another by intervals that are within the limits of resolution of the microscope objective used.

(3) That there is sufficient difference of refractive index between the particles and the medium in which

they are immersed. Only under certain very limited conditions can the full resolving power of the best oil-immersion objectives available for visual work (those in which N.A. = 1·4) be secured by this means. The limits in biological work are less than this, and are imposed by the refractive index of the medium in which the objects to be examined are immersed. As these are rarely widely different from water (with a refractive index of 1·33) it follows that the N.A. of any objective used could not exceed about 1·27. In practice the use of even this N.A. introduces difficulties when there is but a small difference of refractive index between object and medium. The method that appears to be most satisfactory, therefore, is to use an *illuminator with such an illuminating angle that it* admits of the use of an objective of 1·20 N.A. for all preliminary and routine observations. The highest practicable N.A. 1·27 is reserved for use in cases where circumstances are favourable, a point that can only be *determined by experience. The highest practicable* resolution, therefore, by dark-ground methods is that which enables an object of the order of 0·35μ to be seen and perfectly resolved, although much smaller bodies may be rendered visible and some of their physical properties determined. The limits of dark-ground methods in the search for filterable viruses are therefore obvious, but it has been found in practice that much preliminary work can be done. The only other method likely to be of service is, therefore, to use light of a short wave-length as indicated already. Approximately a body may be photographed of one-half the size of the wave-length used. The simple formula governing resolution is given by the relation, $a = \frac{1}{2}\lambda/\sin a$, where λ is the wave-length of the light employed when passing through the medium used, and a is the angle emitted by half the diameter of the back lens of the objective. Thus the value of d, which is the limiting distance between two particles, or the size of a single particle if a correct image is to be seen, can be reduced by increasing aperture or decreasing the wave-length of light used as an illuminant. The former factor is determined by the objective and for visual work cannot be increased. The latter can in theory be altered to any extent, and the usual expression for attainable resolution $\frac{\lambda n}{2\mu \sin a}$ can be diminished so that a filterable virus of any probable size should be resolvable. This is at least what theory indicates, and the direction of experimental work in the department of applied optics is to make such radiations available as are needed for any particular purpose. The present position is not discouraging, but it is admitted that many practical difficulties have yet to be overcome.

It follows, therefore, that there are at present only two methods of attack if a microscopical image of a filterable virus is to be obtained :—

1. The observation of the living material by dark-ground illumination methods in which visibility would be secured in terms of the size of the particular virus.

2. The use of light of short wave-length (that is by means of invisible radiations) resulting in higher resolution, proportionate to the wave frequency.

Both of these methods exclude any process such as staining, in which changes will certainly occur owing to the preparation or fixing of the material. Gye has already referred to the difficulties he experienced in endeavouring to demonstrate organisms in infective material. It is evident that in cases where the body to be observed is below the limits of microscopical resolution, any staining method would be useless. Even more, such processes would destroy the only recognisable characteristic that such bodies possess, the difference that there might be in physical, and particularly in optical qualities, between them and inert particulate matter. In the dark-ground arrangement this would be evident mainly in terms of visibility, but by the use of ultra-violet light it is possible to obtain a real image of a small body providing a short enough wave-length is used.

Dark-ground Illumination Methods.

The apparatus used for this method may now be briefly described. The source of light is a quartz mercury-vapour lamp of the non-vacuum type as designed for microscopy. Colour screens are used to give either monochromatic blue, green, or yellow. The green line in mercury is peculiarly suitable as it is a narrow one and so approaches closely to a true monochromatic light source. Further, as this line is in that part of the spectrum to which the eye is most sensitive it is possible to work with light of low intensity, a point of the utmost importance in dark-ground work.

It is commonly stated, even in text-books, that a powerful light source is necessary, but this only results in such irradiation from larger particles that all fine detail is lost. A stable, well-made microscope is essential as all adjustments must be made with the utmost care. Thus, perfect centration of every part must be secured and the slide and cover-glass must be truly normal to the optical axis of the microscope. Full instructions for setting up a dark-ground illuminator will be found in the Special Report Series No. 19 issued by the Medical Research Council. The illuminators used have been designed to work with 2 mm. apochromatic objectives of 1·2 N.A. and 1·27 N.A., and the whole outfit is made by Messrs. R. and J. Beck, Ltd. Both these condensers work at their best with slides of the thickness of a No. 2 cover-glass. The material to be examined is therefore mounted between two cover-glasses and these are held in a chamber designed for the purpose. Provision is made to ensure that the layer under examination is as thin as possible, regard being paid to the necessity of preventing undue compression. A semi-darkened room is essential for this work, and the illuminant must be so shielded that no direct light reaches the eye at any time. Another essential is to provide means for reducing the light intensity without altering its quality. This is best secured by using semi-platinised glass screens prepared by the method described in the writer's book on photomicrography. A high-power compensating ocular × 18 to × 25 is necessary for final observations and the objectives mentioned will tolerate these perfectly.

The Microscope for Ultra-violet Photography.

The mechanical part of the microscope used is of special construction, as no ordinary one would fulfil the required conditions. Its essential features are great stability and high accuracy of all movements, and its general design is seen in Plate I., Fig. 1. Both the coarse and fine adjustment A_1 and A_2 are actuated through a large accurately-cut screw of the type usually employed on an interferometer, the bed being a heavy casting of girder type supporting the whole. The objective and ocular are carried on separate carriers O_1 and O_2, with no body-tube between them as in an ordinary microscope. This ensures that the adjustment of either optical part does not disturb the other. The mechanical stage is strongly supported so that it is truly at right angles to the optical axis. The two milled heads A_4 control the movements of the object on the stage within certain limits, but the quartz slide is held in a novel manner to give some freedom of movement by hand, while ensuring that the slide is always kept in close contact with the stage, a matter of moment in ultra-violet work. The combined dark-ground and ultra-violet light illuminator O_3, described later, is supported on a strong centreing sub-stage, which is moved by an accurate screw controlled by the large graduated head A_5. This is, in fact, a divided circle enabling the dark-ground or the ultra-violet light illuminating apparatus to be accurately focussed in any wave-length. The mercury-vapour lamp M_1 is mounted on a subsidiary optical bench which is arranged at right angles to the axis of the microscope. At M_2 a reflecting prism is mounted which can be swung into line, thus enabling the beam of light from the mercury-vapour lamp to be projected into the microscope. When the prism is swung out of line ultra-violet light from the spark-gap S_1 is projected by the quartz lens S_2 through the quartz prism S_3, and so into the central part of the microscope condenser. The arrangement therefore admits of either illuminant being brought into use by simply deflecting the prism M_3. This description is of necessity superficial, and assumes some knowledge of the orthodox methods of ultra-violet light microscopy, a full description of which by the writer can be found in the "Dictionary of Applied Physics." One of the main differences in principle here introduced is that focussing in any wave-length desired is performed in reference to the dark-ground image seen in the green line in mercury wave-length 546 μμ. Focussing by means of the fluorescent image is both difficult and dangerous owing to the action of ultra-violet light on living organism. Changes can be set up which might be regarded as normal appearances in the organism. The actual exposure, therefore, of any material to ultra-violet must be the shortest possible. There is no reason to regard the action on living organisms as a trigger action, a certain time factor is involved, but precautions must be observed to ensure that no change due to the light itself is set up. A long series of investigations on the action of ultra-violet on bacteria has been carried out so that this part of the subject is understood; an account of these experiments will be published in due course. There is no reason to regard the filterable viruses that have been under observation as more sensitive to ultra-violet light than ordinary bacteria; there is, in fact, some evidence that they are less sensitive, but this point again requires further investigation. The actual microscopical method employed has therefore been the composite one indicated, and consists of the use of a high aperture dark-ground illuminator already described, mounted concentrically with and encircling a quartz condenser. The former secures visibility and is used for purposes of search and location; the latter is available for use with any suitable ultra-violet radiation and enables a transmitted light image to be secured on the photographic plate. The problem of the best quartz objective to use is still only partly solved; much remains to be done to ensure that the best result should be obtained in any given wave-length. In collaboration with my colleague, Mr. John Smiles, this part of the work is being attacked with every evidence that success will follow. One photograph is shown in which light of 257 μμ wave-length is used, and this is certainly the shortest wave-length recorded as having been so applied to microscopy.

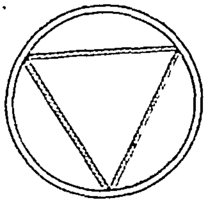
FIG. 4.



Methods of Cultivation.

Cultural methods have been devised and carried out by Gye and are described by him in the foregoing paper. It was, however, found necessary to design some arrangement by which it could be determined whether colonies were developing, and to examine these colonies in situ. From the nature of the growth obtained in fluid there was some reason to doubt whether it would be possible to obtain growth on solid media. Further, as the quantity of growth in fluid, in relation to the volume of medium, is not so prolific as with ordinary organisms, it was regarded as probable that any colonies obtained would be few in number and small in size. A means of examining the surface of serum-agar was therefore desirable in which a 2 mm. oil-immersion objective could be used. Thus it was really necessary to apply to the medium for the detection of colonies a means that would ordinarily be used for the detection of organisms. Briefly, the arrangement that has been found successful is seen in Figs. 3 and 4. An ordinary test-tube is taken, preferably of rather large size, and into it three thin glass slips are introduced in the configuration seen in Fig. 3.

These three slips form a triangle in plan, Fig. 4, and are of such a width that they are free to move in the direction of the length of the tube but cannot

move in any other way. They dip into the agar medium seen at the bottom of the tube, and when the agar solidifies are quite stable. The agar is melted, the serum added in the ordinary way and inoculated with the infective material. After inoculation and before solidification the tube is tilted so that the agar runs along the tube and touches the external face of each slip of glass in turn. The amount of agar left on the glass is determined by the temperature, but it is always possible to repeat the tilting process, several times if necessary, until enough medium remains. The tube containing the three slips is incubated and at any suitable period one slip is removed for examination, the remainder going on for a longer period if desired. Either glass or quartz slips may be used so that examination is possible by the dark-ground method or photographs can be taken in ultra-violet light.

In either case a cover-slip of glass or of quartz is placed on the slide so that cedar-wood oil or glycerine may be used as an immersion medium. The serum-agar usually has sufficient surface moisture to secure optical contact between cover-glass and agar layer. It is doubtful whether colonies would have been detected without this method, and a fuller description will be published later by Mr. F. Welch, who has taken so large a part in working out the details.

Description of Combined Illuminator.

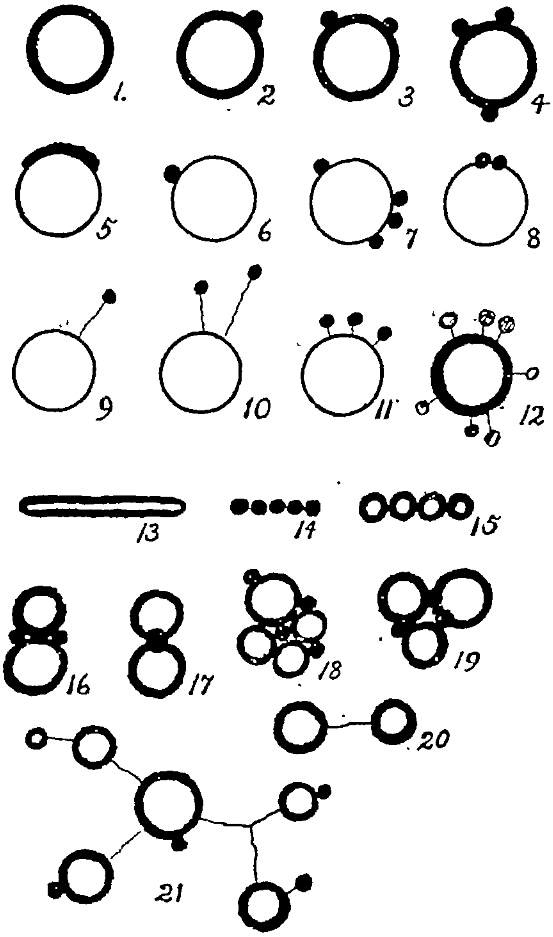
The design of this double purpose illuminator is seen in Fig. 5. The front lens of the central quartz condenser is seen at C, the other two lenses of this combination are D and E. The front lens is in glycerine immersion contact with the quartz slide F, on which the object is supported. The outer quartz ring B is part of the dark-ground illumination appliance and is mounted as shown to transmit the dark-ground beam without alteration of direction on striking the quartz lens C. It will be appreciated that this lens C is an essential part of both systems (in the drawing the closely dotted parts are of quartz, while the wider dotting indicates glass). The ultra-violet light therefore passes through the quartz system in the direction K, as shown, and is focused at the point of observation. The dark-ground illumination, portion A, is an annular glass reflector substantially as shown, which transmits its illuminating beam of visible light also on to the point of observation. By sliding a central stop into the apparatus the quartz system is obscured, while the outer dark-ground portion is covered at will by an annular stop. It follows, therefore, that either part may be used by simply inserting the suitable stop. The light energy required for ultra-violet work is supplied by a high-tension alternating spark between suitable metallic electrodes. The electrodes are selected to give any required wave-length, and a fuller description of this will be found in the author's book on Photo-micrography, now in the press. The method of focussing the image in ultra-violet work has hitherto been by means of a fluorescent screen. The image formed by the quartz ocular is thrown on to such a screen, and is then observed by a short-focus telescope. Focussing by this means is always difficult and sometimes impossible, if the object is a translucent one; further, it entails considerable exposure of the object to ultra-violet light. To minimise the difficulty small mercury droplets may be deposited by sublimation on the quartz slide before the material under observation is mounted. Such droplets can be deposited in almost any order of size by variation of temperature of the mercury and time taken for its deposition. Some droplets are seen as dark discs in Plate I., Fig. 8, and this method has proved of value. The combined illuminator has in most cases, however, rendered their use unnecessary, as visibility can usually be secured sufficiently to focus an image in monochromatic green light, and with the accurate microscope described the focussing in ultra-violet becomes a purely mechanical process.

Observations.

The microscopical search for any filterable virus had been prepared for in part by a continual effort to improve the mechanical and optical parts of the microscope, and some definite advances had been made before any material was available. During the war some experimental work on trench fever suggested that something might be done by studying the optical characteristics of infective material. Further, a considerable amount of work had been done with bovine pleuro-pneumonia, as this appears to be the smallest organism known to grow under ordinary bacteriological methods of cultivation. There was, however, no cultural material available of an undoubted filter-passer until the successful cultivation of the Rous fowl sarcoma by Gye. The earliest efforts to observe this organism were of the simplest character, and consisted of the careful observation of uninoculated culture-media side by side with observation of inoculated tubes of subsequently proved infectivity. Dark-ground illumination as described already was employed, and to ensure that the comparison should be exact two microscopes of similar design and with the same optical equipment were set up. Thus infective and non-infective material could be examined and compared under identical conditions, an arrangement that has proved of great value. All the conditions described herein as being essential for accurate observation were carefully observed. Further, as a control, cultures of pleuro-pneumonia were kept going similarly, and observations were made on this organism in the same way. Any tube of infective material that contained bodies not to be seen in a similar uninoculated tube was then examined under the combined microscope, and if practicable an ultra-violet photograph obtained. Thus a dark-ground visual image was observed and ultra-violet photograph obtained that under favourable conditions would give an image of an isolated element of structure down to an order of size of 0·075 μ. The observations on pleuro-pneumonia were all carried out on living material, and not in reference to stained preparations. These are still being carried on by my colleague Mr. John Smiles at this institute, and will be described fully by him in due course. Briefly, however, these observations lead to some tentative conclusions. Thus the pleuro-pneumonia organism is a small particulate body about 0·2 μ diameter which can only grow and reproduce itself under certain conditions. The particulate form is accompanied by and is dependent for its reproduction on a larger spheroidal body which develops from the particulate form and which then forms the host on which the particulate form can develop further.

Fig. 6 shows diagrammatically the sequence of events as we understand them at present. After about 20 hours a tube that has been inoculated from an agar surface colony will show a number of spheroids that may be represented as No. 1. A few hours later a small refractile dot is seen on one part of the spheroid as No. 2, subsequently developing further bodies as in 3–4. Some spheroids appear to have a thickened wall, while others are thin and of low visibility, but recent observations suggest that this apparent thickening is due to a number of particulate bodies below the limits of size that can be visually resolved. The attached particle then tends to move away from the spheroid, but is still attached to it. This attachment is rarely observed visually, but ultra-violet photographs show it to be a fine filament which is derived from the spheroid and gives to the latter an amoeboid appearance. Some particles soon develop into small spheroids and form groups, as in 16, 17, 18, 19, each of them developing attached particles substantially as shown. In most cases, however, the spheroid tends to disintegrate, or at least become less visible, and finally gets into an unstable physical state, somewhat as shown in 12 and 21, where the central spheroid is still evident but is surrounded by a number of smaller spheroidal bodies. This formation is quite characteristic, but can only be appreciated when actually seen under the microscope. The grouping and movement in fluid is an interesting physical phenomenon in which a rotating spheroidal body unevenly loaded with particles appears to assume a form suggesting a spiral disposition. That the particles can and do develop into spheroids has been proved by careful filtration experiments. Thus a fluid culture has been filtered by us through a Bechhold collodion membrane of such porosity that it passes the particulate forms but keeps back all visible spheroids. The filtrate was incubated for 12 hours at 37° C. without any evident change, but a fresh tube of serum broth inoculated from it and incubated during the same period show that all the particulate forms had developed into spheroids, and the full life-cycle ensued. The explanation of the life-cycle may, therefore, be that the spheroids take the place of the living cell in providing conditions suitable for reproduction. In very young colonies of pleuro-pneumonia (see Plate I., Fig. 2) the particulate forms do apparently divide for the first few hours only, and are then immersed in some excretory material which reduces their surface-tension. Soon, however, the spheroids develop on the outer edge of the colony, and further reproduction takes place on these in the manner described. The argument is too long for full extension here, but it does appear to be the means by which the difficulty of subdivision by a small body is overcome. It is certain that this organism does not divide in the same way as do ordinary bacteria. The difficulty of growing them artificially, particularly on solid media, suggests that some special conditions are necessary, but speculation is futile until the exact physical conditions are better understood. A long series of comparative observations on cultures, all of which have ultimately been proved by animal experiments to be infective, has led to the conclusion that the same type of phenomenon, but on a smaller scale, is to be observed in the Rous fowl sarcoma, mouse sarcoma 37/S and latterly in human carcinoma, as can be seen in cultures of pleuro-pneumonia. In no essential point is there any difference, except that the cultures from malignant growths are slower in developing and do not produce such rich cultures. Probably no single factor has hindered the cultivation of filterable viruses so much as the assumption that a culture in broth, for instance, must become opalescent, or that a growth on solid media must develop colonies easily visible to the naked eye. If as we think probable the spheroids are an essential part of the life-history of these organisms then, owing to their low refractive index, they would require to be present in impossibly great numbers to produce evident cloudiness. The fluid cultures from malignant growths always remain clear; on solid media the colonies are so small that they require the use of a high-power objective to see them. The incubation period has not usually exceeded seven days, and examination of the cultures and similarly incubated uninoculated tubes has been made from three days onwards. During that period the same life-cycle has been observed in all cases as that seen in pleuro-pneumonia. Observation is more difficult than with pleuro-pneumonia owing to the small size and lower visibility of the malignant growth viruses. The microscopical technique has, therefore, to be carefully adapted to these more exacting conditions. Unless considerable care is exercised the spheroids may easily be confused with other spherical bodies occurring in most organic fluids. This can only be obviated by a careful preliminary study of uninoculated culture-media.

FIG. 6.



Diagrammatic representation of bodies seen in cultures of bovine pleuro-pneumonia.

Description of Plates.

PLATE I.

FIG. 1.—Microscope described in text.

FIG. 2.—Young colony of bovine pleuro-pneumonia photographed in ultra-violet light. × 1200.

FIG 3.—Edge of an older colony showing spheroids. × 1800.

FIG. 4.—Young colony showing particulate form. Dark-ground illumination. × 1850.

FIG. 5.—Older colony showing development of spheroids. × 1850.

FIG. 6.—The edge of a young colony of *M. pyogenes aureus*, photographed in ultra-violet light to show normal development of an organism. In this case the line of subdivision is seen before the organism changes its external form.

Figs. 2 to 6 are colonies grown on slips by the method described.

PLATE II.

FIG. 1.—Rous fowl sarcoma colony on agar slip. Dark-ground illumination. × *1850*. *The particulate* bodies are seen centrally in small bright masses, the spheroids developing on or near the edge.

FIG. 2.—Rous fowl sarcoma. An isolated spheroid with attached particle. Dark-ground illumination. × 1850.

FIG. 3.—Same as Fig. 2, but photographed in ultra-violet light. The attached particle is seen to be a small spheroid. × *2000*.

FIG. 4.—Mouse sarcoma. 37/S. Colony on agar slip. Dark-ground illumination. × *1850*. Considerable development of spheroids.

FIG. 5.—A small portion of the colony photographed in ultra-violet light. Wave-length 275 μμ showing that the spheroids may depart rather considerably from a spherical form at some stages of growth. × 2200.

FIG 6.—Same as Fig. 5, but photographed in ultra-violet light. Wave-length 257 *μμ*. × 2200. Showing the ultimate particulate character of the spheroids. From this and other photographs in the same wave-length it is estimated that the particulate form of the virus is of the order of size of 0·075 μ. It is *certainly appreciably* less than 0·1 μ, as resolution cannot be obtained with any greater wave-length.

FIG 7.—Human carcinoma. Colony on agar slip. Dark-ground illumination. × *1850*. *The same general characteristics* are to be seen as in Figs. 1 and 4.

FIG 8.—A small portion of the edge of a larger colony showing spheroids interspersed with particulate bodies. × 1850.

FIG. 9.—A portion of the edge of the same colony as seen in Fig. 8 photographed in ultra-violet, light wave-length 275 μμ.

The general conclusions to be drawn from the photo-micrographs are that the developmental stages in each of the above are similar. It is feared that the reproduction will not show so well as the original negatives, particularly in those done in ultra-violet light. The difficulties are greatly increased owing to the relative opacity of serum-agar to ultra-violet light, the possibility of obtaining photographs at all being due to the thinness of the layer of culture medium. In addition, the negatives are very thin and *lacking in contrast, although they do in the originals* show much delicate detail.

NOTE ON THE PRECEDING PAPERS.

By J. E. BARNARD AND W. E. GYE.

The separate parts of this investigation have now been described, and it remains to indicate how far the results obtained fit together. Our belief that the small bodies seen and photographed are the actual virus depends partly upon the fact that control uninoculated tubes of medium have been invariably blank, and partly upon the correspondence between the microscopical findings and the results of experiments upon animals. *This correspondence—allowing* for the real difficulties in both parts of the common task—has been so close that, although final proof has not been attained, we are convinced that our conclusions are sound. By *final* proof we mean the *cultivation of the virus from a single* colony, or if possible from a single spheroid, and the production of a tumour with the culture thus obtained. This work has been under consideration for a long time, and will be attempted when circumstances permit.

THE

Bowman Lecture

[ABRIDGED]

ON

THE FOUNDATIONS OF VISION.

Delivered before the Convention of English-Speaking Ophthalmological Societies on July 16th, 1925,

BY SIR JOHN HERBERT PARSONS, C.B.E.,
HON. D.SC. (BRISTOL), F.R.C.S. ENG., F.R.S.

[AFTER making introductory reference to Sir William Bowman and his work, the lecturer went on:—]

I propose to delve into the very foundations of the physiology of vision in the hope that a survey of the facts brought to light may elicit some general principles which will clarify our knowledge and point the way to further research.

In so far as the quest is successful its utility will not be limited to vision and to ophthalmology; its repercussions must inevitably be felt in the whole domain of the physiology of the *senses* and in the psychology which is the conscious expression of that physiology. For our waking life is a continuous cinematographic exhibition, in which varying perceptual patterns succeed each other upon the screen of each individual's experience. *Each* pattern is, in psychological language, a "*presentation*," a living picture, in which one feature occupies the focus of attention, surrounded by other more faintly apprehended features which form a relatively indifferent field. It *must not* be *supposed that any* such picture is a purely visual presentation, such as we see in a picture gallery. It is a composite picture made up of elements derived from all the so-called senses, and perhaps the object of consciousness is simply to combine and synthesise these diverse *factors*, in a way which is incomprehensible when viewed simply from the standpoint of the summation of physical quantities. Yet in man the prepotent factor is generally the visual factor, just as in many lower animals the prepotent factor is that derived from the sense of smell.

INTEGRATION OF PHYSIOLOGICAL IMPULSES.

The integration of these diverse physiological impulses is an active—kinetic—process, and it manifests itself in kinetic consciousness. But there are hierarchies of integration, and when a lower level integration has proved sufficiently serviceable to any given species it becomes part and parcel of the make-up of the individuals of the species. It then generally assumes the characters of potential consciousness, or in common terms *is relegated to the "unconscious."*

Further, there are many such integrations at every level—and there are many levels, only great groups of levels being collected within the confines of such terms as reflexes, instincts, and so on. Physiologically, the lower levels are, in vertebrates, associated with the activities of the spinal cord and medulla; higher levels with the mid-brain and thalamus; higher still with the palæo- and neo-pallium.

There are comparatively simple integrations and there are integrations of simpler integrations, forming different "patterns" *in* each level and *at* each level. And the most important point is that *all these patterns are of biological significance*—they are adaptations in the service of the individual or the species. Hence the most significant features of any pattern are themselves extremely complex. What I mean can be best shown by an example from ontogenesis. In very early days of life a child's attention is attracted by a bright light, and the eyes are moved so that the image of the light is formed on the macula of each eye. *A child is soon most attracted towards its* mother, and its behaviour towards her differs according to the tone of the mother's voice, her facial expression, and so on. Now, facial expression is a very complex visual presentation, and it is scarcely conceivable that at this very early age the child has succeeded in accurately correlating the innumerable visual impulses into which a facial expression can be analysed. We must *rather regard the child's impression* as a psychological pattern made up of the integration of a number of relatively undifferentiated auditory, visual, and other complexes, of which the still relatively undifferentiated visual complex forms the *focus*. It *responds to this complex* by appropriate behaviour simply because through countless preceding *generations its ancestors have* responded *to similar* and even less differentiated complexes.[1] The lower down the animal scale the less differentiated are the *complexes to which the individual responds*—and his responses are *biologically* determined—i.e., they are strictly utilitarian. Hence we conclude that the behaviour response is dominated by the psychological pattern, and that higher patterns dominate lower patterns. *But*, since the lower patterns are more primitive they are the least vulnerable—teleologically because they are concerned with vital processes upon which the survival of individual and species depends. The higher patterns are more highly differentiated and therefore more vulnerable. So that even these complex psychological patterns can be divided into two great groups—one, protopathic and of vital import, and another epicritic and of gnostic import.

PROTOPATHIC AND EPICRITIC SENSIBILITY.

I have adopted the terms protopathic and epicritic from the work of Head and Rivers on the tactile sensibility, feeling assured that the fundamental conception is justified, though I do not agree with all the detailed conclusions arrived at by Head.

Using the terms in the wider sense, we may say that the cognitive element of the crude protopathic response is diffuse, vague, and ill-defined. There is reason to think that the adequate stimulus produces the maximum response at the threshold—the reaction is of the all-or-none variety. The higher differentiation of the cognitive element introduces differentiation of another nature. The response, while retaining many of the characteristics of the protopathic response, especially as regards its quality, is better defined, susceptible to finer gradation, endowed with more accurate local signature and discrimination, less charged with affective tone, and of greater gnostic significance. This higher differentiation of sensory responses may be termed epicritic in contradistinction to protopathic. It should be noted that it is to be regarded as differentiated and evolved from the protopathic; and just as a highly differentiated cell in the multicellular organism still retains the fundamental characteristics of a living cell in spite of its special differentiation, so each epicritic sense retains the fundamental quality of the protopathic.

The crude protopathic sensibility was essentially utilitarian in the most fundamental sense; upon it depended the survival of the individual and the species. So important is it that it cannot be wholly replaced by the more delicate epicritic mechanism. Hence it is found to persist alongside the epicritic in most of the senses even in the highest animals, though generally modified from its primitive character.

Moreover, the crude primitive protopathic sensibility had to possess that *potential plasticity* which permits of differentiation along many lines. The more highly differentiated epicritic sensibility lost perforce this type of plasticity. Endowed, however, with richer and more sharply defined cognition it was eminently suited to provide a more active, *dynamic plasticity* within a narrower field.

The protopathic phase is seen in its most characteristic form in the lowest vertebrates; the epicritic in the highest. Between the two are many gradations of each which are difficult to unravel; but both anatomical observations and physiological experiments support the view that there is a dual mechanism at work.

[The differentiation of tactile sensibility into protopathic and epicritic was then discussed, and described in various animals.]

THE MOTOR FUNCTIONS OF VISION.

Visual organs of an extremely primitive type occur very low down in the animal scale. At first they consist of a single receptor cell, which like nearly all receptor cells, is generally provided with hair-like processes. Like other receptor sensory cells they are provided with diplosomes, and often fibrils can be shown passing from the diplosomes into a nerve-fibre attached to the proximal end of the cell. Even at this lowly stage the visual cells are almost always situated in direct relationship with one or more pigmented cells, though this is not absolutely essential to the functioning of such cells as visual cells.

It may be considered definitely proved that these cells respond to luminous radiation, and give rise to appropriate motor responses in the organisms in which they occur. Thus the one primitive and indubitable response to the visual impulse is *motor*. What, if any, are the other responses is a matter of conjecture.

The motor response in the lowest forms is a tropism—a movement either towards or away from the light. The organisms certainly respond to wave-lengths which to us are luminous, but we are not justified in concluding that the range of spectrum which is adequate to their visual organs is the same as that adequate to ours. It may be less or more; and further research is needed on this point. Thus, it may well prove that the organs respond not only to wave-lengths which are luminous to us, but also to infra-red and ultra-violet radiations. It is only what might be expected if the crude protopathic sensation of these organisms should prove to be an undifferentiated temperature-luminous response.

The essential feature of these tropisms, whether positive or negative, is that they are directional responses, and as such are the germ of that projicience which reaches its highest development in the visual sense of man.

[After referring to the visual organs in primitive vertebrates, such as the amphioxus, the lecturer proceeded:—]

VISION IN RELATION TO EQUILIBRATION AND ORIENTATION.

"It is clear that in the visual functions of this animal we have to do only with very *primitive*, essentially *vital visual* functions. The organs do not apprehend objects, but serve merely to regulate the posture of the body in relation to the light (photostasis)" (Kappers).[2] In other words, the sensation is purely protopathic; and the fundamental protopathic response to light is motor—i.e., postural.

It is noteworthy here that in certain invertebrates—e.g., hydromedusæ—some possess simple pigmented ocelli, whilst others have static organs with statoliths, similar to the otoliths in the ear. The function of the static organs in the orientation of the animal is undoubted, and it would appear that at this lowly stage ocelli are capable of fulfilling the same purpose (Hesse).[3]

The immense importance of vision for equilibration and orientation is liable to be lost sight of, or at least underestimated, when dealing with the visual functions of man; for there the static functions are overshadowed by the more patent dynamic functions, and both are overwhelmed by the highly developed sensory and cognitive functions. A study of the anatomy of the central nervous systems and of the behaviour of vertebrates, however, demonstrates the supreme importance of photostasis in the life-histories of these animals from the lowest to the highest. Throughout, in the mid-brain, we find an elaborate coördination centre for gravistatic and photostatic reflexes, of which the afferent impulses are predominantly protopathic. This region is the great meeting-place of primitive protopathic sensory impulses—optic, static, tactile, olfactory and gustatory,—the median longitudinal bundle playing an important rôle as a collecting tract. In fishes the gravistatic system is enormously reinforced by impulses from the lateral lines, impulses which convey impressions of pressure and mechanical vibrations, controlling the movements of the animal with regard to depth below the surface of the water, and propinquity to solid obstructions.

[The lecturer then adverted to the nervous levels and paths concerned in vital reflexes in various animals.]

Clinical observations, and especially Brown-Séquard lesions, show that all the protopathic fibres—mediating pain, temperature, and undifferentiated touch—have a cell-station immediately after entering the cord, and are then relayed into Edinger fibres which decussate in the anterior commissure and pass up in the lateral columns of the opposite side to the medulla, mid-brain, and thalamus. The epicritic fibres—mediating finer tactile discrimination, muscle and joint sensibility, and deep sensation—pass up the cord in the posterior columns to the nuclei cuneatus and gracilis, and are thence relayed to the median fillet, decussating only when they reach the medulla (Petrèn, Fabritius, Brouwer). The epicritic system in the cord is therefore a collection of fibres carrying impulses specially concerned in *stereognostic* perception. It cannot, however, be admitted, with Head, that a perception such as the discrimination of the distance between two compass points placed upon the skin is directly transmitted by any fibres in the cord. Such a perception involves higher syntheses than the spinal cord is capable of, and it is, indeed, inconceivable how it could be conducted by any single tract. Epicritic tactile sensibility mediates finer discrimination by finer differentiation of the crude protopathic sensation, and the psychological manifestations of this differentiation are more minutely accurate local signature and qualitative differences of greater cognitive (as opposed to affective) import. Thus, the protopathic sensations are of more immediately vital, the epicritic of gnostic import.

The *foundation of equilibrium* is posture, and the key to the solution of the problem of posture was the discovery of decerebrate rigidity by Sherrington.

Magnus and de Kleijn divide postural reflexes into two great groups—static and stato-kinetic. The *former deal with changes in posture of the otherwise* stationary animal; the latter with movements of the animal. The stato-kinetic reflexes are the more complicated, and in them the semicircular canals play a large part, whereas only the otolith organs are involved in static labyrinthine reflexes.

Static reflexes are further divided into two groups—postural reflexes proper (*Haltung*) or standing reflexes (*Stehreflexe*), and righting reflexes (*Stellreflexe*).

Standing reflexes are accompanied by *compensatory eye movements*. The tonic labyrinthine ocular reflexes are exhibited when the position of the head in space is altered, and consist of vertical and rotatory deviations. If the head is rotated to the right (right eye down, left eye up) the right eye moves upwards *and the left eye downwards. If the head is rotated* upwards around the bitemporal axis (as in affirmation), the eye undergoes torsion such that the top of the vertical meridian of the cornea moves forwards towards the nose. It will be seen that the labyrinthine reflexes are of such a character as to retain the visual field so far as possible in its normal orientation; but *in no case is this effect fully accomplished.* The effectors of the labyrinthine ocular reflexes are the superior and inferior recti and the obliques. The lateral recti play no part.

The tonic ocular reflexes initiated in the neck muscles are demonstrated in lateral flexions (negation) of the head. When the head is turned to the right the right eye turns forwards (towards the nose), the left eye backwards. Here, too, the eye movements are compensatory, and the lateral recti are involved.

The combined effects of the neck and labyrinthine reflexes are almost completely compensatory, so that the orientation of the field of vision is maintained in spite of the (passive) movements of the animal. When active movements of the animal occur stato-kinetic labyrinthine reflexes are set in action by changes in velocity owing to stimulation of the semicircular canals. These also lead to vertical, horizontal, and rotatory deviations. "These reactions are such that with a given movement of the head of an animal which is in the normal posture the eyes are moved into the position in which they will later be maintained by the static reflexes, so that they are deviated into the necessary direction at the very beginning of the movement, and there is, therefore, an extraordinarily well-developed correlation of ocular labyrinthine and neck reflexes, by means of which, both in movement and at rest, and in the various physiologically possible positions of the head with respect to the body and in space the correct visual attitude and the suitable correlation of the two eyes are ensured" (Walshe).[4]

Of the righting reflexes certain visual reflexes occur only in those animals which have some degree of binocular vision, and then only in the intact animal. They differ, therefore, fundamentally from all the other reflexes, in that they are subserved by the cerebral cortex (probably the visual cortex).

In active movements the coördinations between eyes and labyrinths are equally important, as are also the compensatory effects of each upon the other. In the primates and in man, with the development of binocular vision, vision comes more and more to dominate the labyrinth, acting vicariously for the labyrinth in case of need. The distance-receptor, smell, was the foundation upon which the neopallium was begun, and upon the distance-receptor, vision, it attained its highest perfection in man. Upon the labyrinth was built the "ganglion of the proprioceptive system," the cerebellum. Just as the cerebrum is the highest—apocritic—differentiation and integration of exteroceptive impulses, so the cerebellum is the highest—apocritic—differentiation and integration of proprioceptive impulses, itself under the domination of the cerebrum for the unification of the animal's "self."

The Sensory Functions of Vision.

The universality of the dual mechanism in the exteroceptive sensations would naturally lead one to seek for evidence of the same duality in vision. It must, however, be remembered that the superposition of an epicritic upon a protopathic mechanism not only leads to the subordination of the latter, but also to alterations in its characters. Protopathic touch is characterised by the intensity of the reaction, though accompanied by vagueness and crudity, absence of exact localisation and discrimination, radiation to distant parts, and pronounced affective tone, usually unpleasant. The response is of the all-or-none variety—i.e., any stimulus which surpasses the threshold produces the maximum effect—there is no gradation. Any reflex motor response is of the same ungraded nature—i.e., it is a "mass-reflex" (Head and Riddoch). When, *after division of a sensory nerve,* epicritic sensibility returns, protopathic sensibility undergoes definite modifications. "Some of its elements persist and combine with elements of the epicritic stage to form features of normal cutaneous sensibility. Certain characters are *suppressed* or inhibited, especially radiation and distant reference. Similarly, *the mass reflex* occurring in complete transverse lesions of the spinal cord is suppressed in the normal subject. In these suppressions "*Such elements as are serviceable are utilised when the later and higher forms of sensibility came into existence. . . . It is only those of early sensibility which are incompatible with later developments which are suppressed*" (Rivers).[5]

The Duplicity Theory.

One of the best supported hypotheses relating to vision is the so-called duplicity theory.[6] According to it, scotopic vision, or vision under low intensities of illumination by the dark-adapted eye, is carried *out by means of the rods,* and photopic vision, or vision under higher intensities of illumination by the light-adapted eye, is mediated by the cones. It would seem at first sight that we have here ready to hand the duality which is demanded by the protopathic and epicritic theory. And, indeed, there are many facts which strongly support this view.[7] Scotopic vision shows many of the characteristics of protopathic sensibility, especially in its vagueness and crudity, its undifferentiated character, and lack of exact localisation and discrimination. Photopic vision shows many of the characteristics of epicritic sensibility, especially in its meticulous exactitude of localisation and discrimination—the highest indeed which has been acquired by any form of sensibility[8]—and in its greater *differentiation qualitatively in the perception of colours.*

On the other hand, special features of protopathic sensation are its "all-or-none" reaction and its tendency to initiate a "mass reflex." The protopathic light-sense, so far as it has been investigated *at present, does not* exhibit either of these characteristics. But if we regard it in its primitive manifestations it is more than probable that it then exhibited both. In higher animals it has become differentiated into the epicritic phases, but still persists in modified form underlying the epicritic manifestations. The primitive protopathic light-sense we must regard as vague, diffuse, and not accurately localised. If it persisted in this form unmodified, when the light-sense became more definitely projicient it would interfere with exact discrimination. The suppression of these features, however, has become complete only in the macula, the area of distinct vision. Further, the projicient senses are concerned with the initiation of anticipatory or precurrent reactions. It is the contact exteroceptors which are specially concerned in consummatory reactions.[9] *Anything in the nature* of a mass reflex action to projicient sense stimulation would frustrate the object of this adaptive mechanism;

hence the modification of such a response from the protopathic light-sense.

But if protopathic vision has lost some of the characteristics of primitive protopathic sensibility it appears to have gained some epicritic characters in its manifestations in normal man. Thus, it shows gradation, as exemplified in the luminosity curve of scotopic vision. Moreover, it is not improbable that in certain conditions it can show some of the qualitative differentiations of epicritic vision under strong intensities of excitation. There is practically no evidence as to what happens to the scotopic mechanism when the intensities of stimulation are such as to educe photopic vision. If the stimulus is increased above the chromatic threshold, what happens with regard to the scotopic mechanism? Is it inhibited, as the protopathic optic thalamus is inhibited by the cortex, which is predominantly epicritic in function? Is it short-circuited—perhaps owing to the complete bleaching of the visual purple—or does it contribute to the brightness element of photopic vision, or does it acquire all the characteristics of photopic vision, contributing not only to the brightness, but also to the other qualitative—chromatic—effects? Now, one of the greatest difficulties, hitherto unsurmounted, of the duplicity theory is the behaviour of the periphery of the field of vision. There is overwhelming proof, derived from peripheral luminosity curves, minimal field and minimal time luminosity curves,[10] that peripheral vision behaves in exactly the same manner as central vision, but with diminished sensitivity. Greater stimuli are required to produce equivalent responses, but if the stimuli are sufficiently great, the differences disappear, including even the qualitative differences, so that the fields of vision for colours extend to the extreme periphery.[11] Anatomically, the peripheral retinal neuro-epithelium consists almost entirely of rods—the scotopic or protopathic mechanism. It seems probable, therefore, that under high intensities of excitation in normal man the protopathic mechanism is capable of giving the same chromatic responses as the cones, or essentially epicritic mechanism.

THE APPRECIATION OF MOVEMENT IN THE LOWER VERTEBRATES.

One outstanding feature of vision in the lower vertebrates is the appreciation of movement. This is an adaptation of the highest biological significance, since upon a rapid apprehension of movement in enemy or prey may depend the preservation of life. It is therefore to be expected that this characteristic will be bound up with the most primitive type of visual sensibility. There is no doubt that great acuity in the perception of moving objects is a prominent characteristic of the panoramic vision of lower animals, both herbivora and carnivora—probably more in the former than in the latter. There can also be little doubt that in these animals, although vision has already undergone some differentiation and has acquired some epicritic characters, it is essentially protopathic, even if not of the most primitive type. If in man the rods are the organs of protopathic vision we should expect them to exhibit those physiological attributes which, when synthesised with other attributes, permit of the perception of movement. And it is, indeed, found that perception of movement is most acute when the image falls upon peripheral parts of the retina. This is very strikingly demonstrated by the persistence of flicker in the periphery when it has already ceased for the same rate of alternation of stimuli at the centre.[12] We might also expect that in recovery from lesions which abolish peripheral parts of the field of vision the appreciation of movements of objects would be restored before the appreciation of shape or colour. Wilfred Harris,[13] in 1897, pointed out that this was so in cases of transient hemianopia following epileptic attacks, and Riddoch[14] has brought forward still more conclusive evidence derived from war injuries of the occipital lobes. The conclusion which Riddoch draws, which is comparable with Head's tracts of tactile discrimination—viz., that a sensation of movement should be regarded as a primitive function of the peripheral retina, cannot be admitted. Like tactile discrimination, the appreciation of movement is a perception, dependent upon change of local sign, and therefore involves a synthesis of such a nature that the peripheral mechanism alone cannot effect. Striking evidence of the part played by the cortex in the perception of movement is afforded by a case of bilateral lesions of the occipital lobes reported by Pötzl.[15] If a strong source of light was moved slowly or rapidly before the eyes the patient did not seem to apperceive the movement of the object, but interpreted it as several separate lights.

The extreme sensitivity to movement is due to the low stimulus threshold of the scotopic mechanism and its capacity for summation whereby subliminal stimuli surpass the threshold if they are reinforced numerically, either by increase in the area excited or by successive excitation of neighbouring points. In addition to these factors, it is necessary that the response should be of short duration, dying away rapidly under continued excitation. This is indeed a very well-marked feature of stimulation of the peripheral parts of the retina. It is usually attributed to rapid fatigue, but it is very doubtful in my mind whether fatigue, properly so-called, occurs in the retina at all. The rapid fading is much more likely to be due to a form of induction, which produces a refractory period.[16]

The all-or-none reaction of the most primitive form of protopathic sensibility negatives not only gradation, except in so far as this can be accounted for by recruitment, but also adaptation in the sense in which this term is used in physiological optics. Yet in man it has become endowed with both. It shows, however, scarcely any trace of gradation in what is commonly described as "form vision."

PHOTOPIC VISION EPICRITIC.

The photopic mechanism, mediated by the cones of the retina, shows all the characteristics of epicritic sensibility. It is minutely graded, following, like other sensations and most perceptions, the well-nigh universal Weber-Fechner law over all ranges of intensity except the very high and the very low. It is not only thus graded in intensity, but also in extensity, displaying minute discrimination as regards local sign. This is the basis of visual acuity, which in the case of contour displacements may reach the extraordinarily high value that s involved in the discrimination of so low a visual angle as 2″ (Andersen and Weymouth).[17]

Photopic vision also shows the richest qualitative differentiations of any sense, its only competitor being hearing. Whereas scotopic vision is under normal conditions capable only of an undifferentiated "vision brute," photopic vision manifests itself in all the colours of the rainbow and a few more.

But, while photopic vision is pre-eminently epicritic in these higher differentiæ, it also resembles epicritic sensibility in general in retaining the fundamental quality of protopathic vision. The mere untoned brightness or luminosity of scotopic vision pervades every photopic response as a brightness which everyone recognises but which is so difficult to define. Thus, Helmholtz says, "I have the impression that in heterochromatic luminosity equations it is not a question of the comparison of one magnitude, but the combination of two, brightness and colour glow, for which I do not know how to form any simple sum and which I cannot further define in scientific terms." The perceptual pattern is still relatively undifferentiated, and at the lowest intensities it becomes indistinguishable from the protopathic pattern.

For if we study the threshold of vision in the rod-free area of the retina we find that the total quantity of light—i.e., the product of the area stimulated and the illumination—must attain a certain value, and it makes no difference how the quantity and the area are varied so long as the product is the same (Riccò).[18]

Here we have a precise mathematical law, which holds for these most differentiated structures, but does not hold for peripheral retina.[19] Asher found that for the range of light intensities used by him, *the apparent size up to a visual angle of 2′–3′ depends* entirely upon the quantity of the light. By varying the area and the intensity of the light smaller areas may be made to appear larger than really larger areas. The so-called "magnitudes" of the stars depend upon this fact. Similarly, with regard to colours, Charpentier showed that the chromatic threshold also depends upon the area stimulated. As might be expected, for the more highly differentiated colour-sense, the law associating area stimulated with intensity is not so simple as for white light. Further, as Abney[20] has pointed out, as the intensity of the light is diminished gradually to extinction of the sensation, a coloured square or disc becomes first an ill-defined fuzzy patch of grey and appears finally *to depart almost as a point. It appears to me that* these liminal stimuli reproduce the characteristics of primitive chaotic sensations, in which size, colour, and other qualities are but little differentiated—in other words, the protopathic sensation.

If Head and his colleagues are correct in saying that the temperature sensations are common to both protopathic and epicritic systems, but differ from the two systems in range, &c., these are comparable to luminosity in protopathic and epicritic vision.

So far as affective tone is concerned it is undoubtedly enhanced in epicritic vision in man, owing to the appreciation of colours. It is, however, probable that the affective tone of protopathic vision in lower animals is much greater than in man; and the *affective tone in man is largely the result of higher*—conceptual—syntheses, mediated by the complex association system of the cortex.

It has already been pointed out that movement is more readily discerned when the images fall upon the periphery of the retina—i.e., in the eminently protopathic area. It is, however, also mediated by the epicritic system in the macular area. There is, indeed, evidence to show that the physiological factors which have already been described as subserving the perception of movement at the periphery also obtain in less evident degree at the macula. Andersen and Weymouth attribute an important function to movement in the binocular discrimination of depth. As already mentioned, they find the threshold extremely low, corresponding to retinal displacements far less than one cone-diameter. They think that this can be explained by visual stimuli giving rise to a complex percept of position, which they call the retinal mean local sign. At least three factors contribute to this: (1) The mutual effect of adjacent retinal elements in either retina; (2) the averaging of the successive stimulus patterns on each retinal mosaic caused by the constant slight eye-movements; (3) the combining of the two simultaneous stimulus patterns presented to the two eyes. They do not, I think, take sufficient account of induction, whereby the irregularities produced by the irregularly distributed cones are smoothed down by inhibition of the unstimulated or relatively unstimulated neighbouring cones, a function comparable to reciprocal innervation. Moreover, as Sherrington has pointed out, this facilitation of visual acuity is an example of immediate induction. He has found that osmic-stained nerve-fibres of 4 μ diameter are visible to the naked eye. Similarly, just as a moving point in the peripheral field is more visible than a line of similar length, direction, and duration, so a row of dots individually below the minimum visible and too far apart for their retinal images to overlap by diffusion becomes visible. Hartridge also says,[21] "Contours of all kinds are met with to a very great extent in ordinary visual observation, and it would appear that the important phenomenon of simultaneous contrast has been specially developed in order that the appreciation of contours should be facilitated. The narrowness of a contour of which the eye can perceive the existence is therefore a matter of far greater importance in vision than the fineness of a grating or the closeness of two double stars that can just be resolved."

EPICRITIC DIFFERENTIATION THE BASIS OF COLOUR APPRECIATION.

Epicritic differentiation reaches its highest development in vision among all the senses, for upon it depends the appreciation of colours. The study of colour vision, however, shows that, complex as it is, it is by no means as elaborate as the vast range of hues which we can discriminate would lead us to suspect. *The late Lord Rayleigh claimed to be able* to discriminate between the hues of the two sodium lines, a difference of less than 1 μμ wave-length, and under favourable conditions 150 or more hues can be detected in the spectrum.[22] Newton, however, proved that all these hues and others outside the range of the spectrum (the purples)—in fact, with very few exceptions[23] every perceptible hue—can be reproduced by the mixture of radiations of three wave-lengths suitably chosen. This is a fact of such profound theoretical importance that in my opinion no theory of colour vision is adequate in which it does not play a fundamental and preponderant rôle. Thomas Young first recognised that the totality of physiological activities comprises far fewer elements than the objective stimuli, *and that a triplex physiological* mechanism, each part of which responds appropriately to spectral radiations, would suffice to explain a vast number of the facts of colour vision, thus reducing the independent variables from an indefinitely large number to three.

It is not my intention here to discuss theories of colour vision. The data in favour of the trichromatic theory are well known, and the arguments against it have been even better advertised. It is clear that if the trichromatic theory is true the explanation of the evolution of epicritic vision from the primitive protopathic form is very much simplified. The theory was founded upon the responses of the eye to mixtures of various light stimuli, and for many years rested upon these facts. Of recent years much confirmatory evidence has been derived from the study of the time relations of the responses. The antagonistic facts were derived chiefly from observations upon simultaneous and successive contrast, and Helmholtz did scant service in attributing these to psychological causes. *Recent work has shown that* many, if not all, of these facts are elucidated by a better knowledge *of induction, and are as* much "physiological" as the facts of colour mixture.

One of the most striking and least explicable facts of colour vision is the eliciting of chromatic responses by pure black and white stimuli. The best known method of producing them is by means of Benham's top, though Fechner had already drawn attention to them in 1838.[24] There can be little doubt that the true explanation in its main outline has been adduced by Piéron.[25] It has long been known that the response to a light stimulus is in the form of a wave of sensation, which, with strong stimuli, rises very rapidly to a maximum and then falls at first rapidly, and then more slowly. With weaker stimuli the curve is flattened out:[26] the stronger the stimulus the more rapid both the rise and the *fall of* the response—according to Piéron both are proportional to the fourth root of the intensity when the cones are stimulated. It has further been shown that the response to red rays * is most rapid, that of violet rays least, and that of green intermediate. When we take into consideration the so-called "hypermaximal phase," the peak of the curve which is the *first stage of the* response, and the time relations as determined by Broca and Sulzer,[27] the colours observed with Benham's top are completely explained, as shown by Piéron's observations and diagrams. What, however, is not so readily explained is that the colours are only observed in juxtaposition with the black lines, and not over the white surface. Piéron's explanation of this fact is obscure and unsatisfactory.† It is probable that the true explanation depends upon reciprocal induction.

---

* This inaccurate terminology is used for the sake of brevity.

By means of a rotating sector or episcotister Charpentier and others have studied the duration of the visual response to a flash of light. The criterion of duration is the critical frequency of alternation of light and dark—i.e., the point at which flicker disappears. When the durations for individual wave-lengths of a spectrum are plotted as ordinates against the wave-lengths as abscissæ, a curve is obtained which is called a "persistency curve." Since the duration varies inversely with a function of the brightness—as proved for a very wide range of intensities by Porter, and confirmed by innumerable observers since[28]—the lowest part of the persistency curve corresponds to the brightest wave-lengths—i.e., lower points mean greater brightness. Obviously, too, if the reciprocals of the durations are plotted against the wave-lengths we obtain the luminosity curve of the spectrum. In fact, flicker photometry is now recognised as the most accurate method of heterochromatic photometry.

ALLEN'S RESEARCHES ON "FATIGUE."

By investigating the effect of so-called "fatigue," with spectral colours upon the persistency curve, Frank Allen,[29] professor of physics at Winnipeg, has discovered a number of facts which are of great importance to the theory of vision.

[The lecturer here entered into the subject of Allen's researches in considerable detail, and finally summarised them as follows:—]

(1) Stimulation of one area of a retina with light causes—

(*a*) *Direct effects* upon that area.

(*b*) *Induced effects* in all other areas—i.e., both in the same eye and in the other eye.

(2) *Direct Effects.*—With both eyes in a condition of moderate photopia:—

(*a*) Stimulation with white light depresses the sensitivity throughout the spectrum.

(*b*) Shading the eye also depresses the sensitivity throughout the spectrum.

(*c*) Stimulation with any given wave-length depresses the sensitivity to this region of the spectrum and enhances it for the complementary colour.

(*d*) With any given wave-length the depressions and enhancements show three curves affecting respectively the red, green, and violet.

(*e*) Stimulation with the equilibrium colours—660 μμ, 570 μμ, 520 μμ, 505 μμ, 480 μμ, 425 μμ—has no apparent effect upon the sensitivity of the visual apparatus.

(3) *Induced Effects.*—With both eyes in a condition of moderate photopia the effects on the unexcited areas of the same and the opposite retina are:—

(*a*) Stimulation with white light enhances the sensitivity throughout the spectrum.

(*b*) Shading an area or an eye depresses the sensitivity throughout the spectrum.

(*c*) Stimulation with any given wave-length enhances the sensitivity throughout the spectrum, the enhancement being most marked in every case in the red, green, and violet.

(*d*) Stimulation with any given wave-length enhances the sensitivity most for the complementary colour.

(*e*) Stimulation with the equilibrium colours has no apparent effect.

As the result of Allen's researches we are able to envisage more accurately the phenomenon of induction. As he has pointed out, they serve to prove most conclusively the physiological—as opposed to transcendental psychological—foundations of contrast. They explain on purely physiological grounds many of the greatest difficulties associated with contrast, such as the divergence from the precise complementary in induced colours (p. 932),[30] changes in hue and saturation after prolonged fixation (p. 933),[30] coloured shadows (p. 936),[30] the "memory colours" of Hering (p. 938),[30] the Ragona Scina experiments (p. 375),[31] some of Abney's experiments (p. 379),[31] binocular contrast (p. 381),[31] Fechner's paradox (p. 609),[32] Bidwell's experiment (p. 618),[32] and some of Edridge-Green's observations (p. 620).[33]

The facts at our disposal do not render an exhaustive discussion of the elementary physiological processes occurring in the receptors, conductors, and synapses very profitable. The only firmly established fact is that visual purple is the physico-chemical substratum of scotopic vision, and hence it is natural to have some predilection for thinking in photo-chemical terms.

CONDUCTION OF VISUAL IMPULSES.

When one comes to conduction of the visual impulses, there is no good ground for imagining that it is different from the conduction of nervous impulses in other nerves. If that be so, the all-or-none character of the response discovered by Adrian and Keith Lucas holds good. The theory of recruitment for the explanation of the graded muscular response to different intensities of stimulation in motor nerves, whereby increased intensity increases the number of nerve fibres stimulated and of muscle fibres responding, meets with difficulties in the case of tactile and visual responses. As already mentioned, it may suffice to explain some of the effects in the scotopic mechanism, but it is not easy to apply it to the single cone bipolar mechanism of the epicritic system.

[Instances of inhibition in visual phenomena were alluded to, especially those of binocular and monocular struggle elucidated by McDougall's work.]

Turning now to the anatomical basis of the lower visual impulses, have we any knowledge or can we reasonably conjecture the structures which mediate the conduction and central connexions of the protopathic and epicritic systems? As is well known, the afferent visual paths from the retina in the optic nerve and tract pass to three so-called primary visual centres—the lateral geniculate body, the pulvinar of the optic thalamus, and the superior colliculus. Of them, those passing to the colliculus are undoubtedly the most primitive phylogenetically, since they are a residuum representing the survivors of practically the whole of the afferent visual fibres in lower animals, which pass to the tectum. Here they form the superficial layer of fibres, and are brought into relation with the bulbo- and spino-tectal fibres. There is no doubt, therefore, that in these animals, going down as low as the cyclostomes, the function of these optic fibres is almost entirely photostatic, and that they are protopathic. The tectum shows histological differences in mammals from the condition in lower vertebrates. The optic fibres are reduced in number and are situated below a layer of nerve cells, and therefore less superficially. Moreover, the efferent cells are raised and somewhat approximated to the optic fibres. These efferent cells send axons to the retina (tect-optic fibres of Ramon y Cajal and v. Monakow) and to the tecto-bulbar tracts. Kappers attributes this approximation to neurobiotaxis, and sees in it an expression of the predominantly reflex function of the optic fibres. "Optic reflexes in mammals are certainly not fewer, but in the primates are much finer than in lower animals."[33] The tectum receives no macular fibres, and has no cortical projection. We may conclude, therefore, that the optic fibres to the superior colliculus in man are protopathic.

There is good reason to think that the great majority of retino-geniculate fibres carry the impulses of the epicritic system, but that those which pass to the ventral nucleus are protopathic.

In primates, and especially in man, some of the optic nerve fibres, both crossed and uncrossed, pass to the pulvinar of the optic thalamus. This increase in the dorso-lateral part of the thalamus is associated with the adoption of the erect posture. It is a correlation area, receiving besides the visual fibres also fibres from the anterior peduncle of the cerebellum (Horsley and Clarke) and the red nucleus (Sachs). It is in near relation with the thalamo-cortical fibres to the arm region of the pre-central convolution, and its development is probably related to the increased importance of the hand and fingers as organs of exploration (Kappers). It may therefore be regarded as a "centre" for the correlation of eye and hand, and therefore of the utmost importance in stereognosis. This view is strongly supported by the fact that the pulvinar has an extremely rich cortical projection to the angular gyrus. There can be no doubt, therefore, that the retino-pulvinar fibres belong to the epicritic system.

---

† Lorsqu'une petite surface rétinienne n'est pas, ou n'est que faiblement excitée au voisinage d'une region qui est le siège d'un processus lumineux et chromatique, l'excitation de cette surface par diffusion comporte une prédominance des processus chromatiques, qui se propagent avec une intensité plus grande que le processus lumineux."

It is easy to correlate these anatomical deductions with the vital import of the reflexes which are chiefly dependent upon protopathic vision, and with the gnostic import of visual sensations which are chiefly dependent upon epicritic vision. It is more difficult, and perhaps in our present state of knowledge impossible, to correlate them with the relatively feeble, but still very appreciable, gnostic import of scotopic vision.

I have built up the argument in this thesis chiefly on the known facts of visual sensations in man, in whom alone we have immediate knowledge of them. The visual organs of lower animals might be expected to afford a vast amount of evidence for or against the theory. It must be freely admitted that the evidence from this source, in the present state of our knowledge, is very ambiguous. Nor should this, indeed, be unexpected. Light-responsive organs are found in nearly all moving animals, including many of the lowest invertebrates. There is, it is true, a remarkable uniformity in the general plan of the structure of the receptor cells; but it is a uniformity which characterises all sensory receptor cells. The mosaic eyes of insects show that it is possible to have a visual organ built on so different a plan from the mammalian eye that scarcely any analogy can be drawn between them.

Confining ourselves to vertebrates we find great diversities within a common type. Speaking teleologically, this was inevitable. Adaptation to terrestial life necessarily involved changes in the visual apparatus, life in the air yet other changes. But, apart from these gross adaptations, each species has become specially adapted to a particular environment and mode of life. In these adaptations vision, whilst nearly always retaining an important rôle, has not necessarily been the predominant sense. It cannot be too forcibly insisted that all the facts of perception are biologically determined. An exhaustive investigation of the correlation of the various senses in different animals could not fail to elicit facts of profound physiological and psychological importance. The most cursory observation of their habits and anatomical structures reveals striking differences, such as the lateral line system in fishes, the colossal lobus visceralis associated with taste in certain fishes, the great development of the trigeminal in cyclostomes, some birds (ducks and geese), the crocodile, &c., the high development of smell in monotremes, dogs, and so on. As is well known, the cortex cerebri was built up upon the basis of the sense of smell, to be replaced only later by a neopallium built up upon the basis of vision, to which man owes his supremacy. Hence the position of the primates is peculiar, and analogies which might well be expected to obtain among them are scarcely to be looked for between them and species of a totally different mode of life.

Moreover, investigations of the vision of lower animals are extremely difficult and have led to very untrustworthy results. We have no certain knowledge of the range of spectral radiations to which lower animals respond, nor the modes of their reactions. The experiments of Hess and others,[3] elaborate and interesting as they are, have led only to tentative conclusions.

The most promising field of investigation from the present point of view is the structure of the retina in vertebrates. The duplicity theory originated in the observations of Max Schultze and Parinaud on the neuroepithelium of diurnal and nocturnal animals. Greeff[4] found that there are rods and cones in the retina of most mammals, amphibia, and fishes, the number of the rods much exceeding that of the cones. In birds cones are much in excess of rods. In most reptiles (lizards, snakes, tortoises) only cones are found; diurnal saurians have no rods, nocturnal no cones (Rochon-Duvigneaud). There are vertebrates possessing only rods—e.g., amongst fishes, rays and dog-fish; amongst mammals, hedgehog, bat, mole, and night-ape (*Nyctipithecus felinus*). There are also animals of nocturnal habits possessing only rods. Owls, mice, and roll-mice have only a few rudimentary cones; rats also possess a few cones. Hess found rods in fowls and pigeons, though they are scanty in the posterior and superior parts of the retina, which are most used in pecking.

So far then the observations seem to confirm the thesis set forth above. But if one investigates the subject more closely doubts arise. It is by no means easy—indeed, it seems to be impossible—to find any definite criterion as to what is a rod and what a cone. The foveal cones in man, for example, are in no sense conical, but resemble elongated rods—and these are the organs of "cone" vision par excellence! The extreme ambiguity is shown by Putter's[5] morphological classification:—

I. Outer limb cylindrical.

(a) Inner limb cylindrical. (1) Foot-piece knobbed—e.g., "rods" of rat and selachian fishes. (2) Foot-piece branched—e.g., "rods" of sparrow, "cones" of macula of man.

(b) Inner limb swollen: (3) Foot-piece knobbed—e.g., "rods" of man. (4) Foot-piece branched—e.g., "cones" of pigeon.

(c) Inner limb filamentous: (5) Foot-piece knobbed—e.g., "rods" of perch, esox, chondrostoma. (6) Foot-piece branched—e.g., green "rods" of frog.

II. Outer limb conical.

(a) Inner limb cylindrical: (7) Foot-piece branched—e.g., "cones" of fovea of sparrow, "rods" of siredon.

(b) Inner limb swollen: (8) Foot-piece branched—e.g., peripheral "cones" of man and birds, "cones" of many fishes, &c.

III. Outer limb filamentous.

(a) Inner limb cylindrical: (9) Foot-piece branched (?)—e.g., "cones" of esox.

(b) Inner limb swollen: (10) Foot-piece swollen—e.g., "cones" of siredon.

An examination of our present knowledge of the comparative histology of the retina is disappointing, and we must await further information before much help can be derived from this source.

In conclusion, though there is much in this thesis which is speculative, the speculation is of that type for which the term hypothesis should be reserved—i.e., it is that form of speculation which is submissible to experimental verification and elaboration—the only form of speculation which is of scientific value. What I wish specially to emphasise is the view that increased knowledge of the psychology of perception, in which in man vision plays a predominant part, must depend upon increased knowledge of the physiology of the special senses. And further, that the advance of ophthalmology also depends upon increased knowledge of the physiology of the eye and of vision. Ophthalmology, in my opinion, has too long been content merely to apply past knowledge. The future advance in the treatment of cataract, for example, will not, as heretofore, consist in new refinements of technique, but will be revolutionised by the biochemistry of the lens. Let us take to heart this great lesson, perhaps the most important lesson taught by the life and work of Sir William Bowman, the master whom we venerate to-day.

THE NASAL SINUSES AS A ROUTE OF INFECTION IN ENCEPHALITIS LETHARGICA.

BY A. LOWNDES YATES, M.D. LOND., F.R.C.S. EDIN.,
CASUALTY SURGEON, QUEEN'S HOSPITAL, BIRMINGHAM; SURGEON, EAR AND THROAT DEPARTMENT, GENERAL HOSPITAL, WOLVERHAMPTON;
AND
STANLEY BARNES, M.D., D.SC., F.R.C.P. LOND.,
HON. PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM.

I. BY MR. LOWNDES YATES.

IN inflammatory conditions of the nasal mucous membrane we are able to recognise four main types of inflammation—namely, Type 1, where the secretion consists of clear mucus, and the cilia are either active or are fatigued by the additional work necessary to remove the mucus, if this is more viscid than normal. Type 2, where the condition is similar to the above, but the inflammation is of a higher degree, with the result that serum and leucocytes are mixed with the mucus, which is then known as muco-pus. Type 3, in which the mucus is altered by fermentation as a result of the number of micro-organisms present within it, so that it is thin and partially toxin-permeable, as a result of which bacterial toxins reach the mucous membrane, causing congestion of this, particularly in the regions of the ciliary tracks. Type 4, in which the mucous membrane is pale, the ciliary action is paralysed, the mucous secretion absent or represented by a thin whitish coagulum or by fluid material, and in which the heightened absorption in cases in which the physical conditions favour the retention of fluid for a period of 20 minutes or so, may be demonstrated by the use of indigo-carmine solution.

Heightened Absorptive Power of the Damaged Mucous Membrane.

In an examination of 23 cases of encephalitis lethargica this type of inflammation has been found in or around the opening of the sphenoidal sinus in all. The significance of this fact had escaped my attention until it was pointed out by Dr. Stanley Barnes, who suggested that the heightened absorptive power of the mucous membrane in these cases afforded an explanation of the manner in which the filter-passing virus reached the tissues. It follows from this, if the above hypothesis is correct, that only such members of the community as suffer from this type of rhinitis or sinusitis in this region of the nose are potential subjects of this disease, and that it is necessary for the passage of the disease from one individual to another that the air-borne and filter-passing virus of encephalitis lethargica should fall on soil previously prepared by inflammation which has resulted in the alteration of the normal mucous membrane to that of sinusitis or rhinitis, with total or subtotal paralysis of the cilia and of the mucous secretion; such alteration having been produced either as a result of a chronic rhinitis or as a result of a single heavy infection of the nasal mucous membrane of the type known colloquially as influenza. In patients who have developed encephalitis lethargica after suffering from a chronic and intense rhinitis for some years, bacteriological examination in almost all cases has demonstrated the presence of either the bacillus of Friedländer or of the pneumococcus, and the well-recognised chronicity of the nasal infection when these organisms are present affords an explanation of the occurrence of type 4 sinusitis in these cases, while in a few cases other organisms were found. In those cases in which a history of an acute or influenzal rhinitis was present, cultivation of the contents of the sphenoidal sinus revealed the presence of the *Staphylococcus aureus* together with the pneumococcus, while in one case hæmolytic streptococcus was found; and it is thought that the well-known proteolytic power of these micro-organisms explains, by the assumption that they have a similar proteolytic power on mucus, the rapidity of the change in the mucous membrane, the inflammation in which is of such intensity that it passes from that of the mucous membrane with normal reaction to that of a type 4 rhinitis within the space of a few days or even hours.

With regard to the finding of the *Staphylococcus aureus* in a high percentage of cases of encephalitis lethargica occurring after rhinitis of the influenzal type, it should be noted that we have only lately found the cultural methods which we have employed slightly favour the growth of this organism, and the observations will therefore have to be repeated. The normal nose by similar bacteriological methods is sterile. If scales of mucus are dry sterilised, dissolved under sterile conditions, and kept at room temperature, the solution retains its colloid character almost indefinitely, but if mixed with a large quantity of living staphylococci it is rapidly autolysed. Small quantities of staphylococci mixed with the mucus appear to die. If the mucus is inadequately sterilised rapid autolysis occurs, which suggests that other organisms besides the staphylococcus can destroy the mucus.

The heightened absorptive power of the mucous membrane can be demonstrated in type 4 sinusitis by injection of either solutions of indigo-carmine or of phenol-sulphone-phthalein into the sinuses, when it will appear in the urine, taking about twice as long to do so as if it were injected into a muscle, but not appearing in the urine in cases of sinuses lined by relatively normal mucous membrane.

Of the 23 cases of encephalitis lethargica examined, seven gave a history of acute rhinitis following sinus pain, generally associated with some degree of ill-health.

From the above considerations it would appear that in the cases of encephalitis lethargica examined, the mucous membrane in and around the region of the sphenoidal sinus had undergone alterations of such a nature as to diminish the secretion and greatly increase the power of absorption from it. Such a condition would facilitate the passage of a filter-passing organism,

and it appears probable that the virus of encephalitis lethargica can enter the tissues with greater readiness when such a condition is present, and therefore this may be a necessary precursor of the disease. It is, however, not possible to speak definitely on this point until this hypothesis has undergone the test of time.

In cases where disease is no longer active but is slowly progressing, the washing out of the sphenoidal sinuses and filling them with eucalyptol paraffin appears at times to effect a marked improvement, but has no effect whatever upon such symptoms as are due to brain lesions. It does appear, however, in practically all cases to prevent recurrences, while in more acute cases the use of eucalyptol paraffin within the nose is well worth a trial alone or combined with washing out the sphenoid.

I am indebted to Dr. G. Eden, of the Queen's Hospital and Hospital for Nervous Diseases, Birmingham, for the provision of much clinical material on which this report is based, and to Dr. R. B. H. Wyatt, bacteriologist to the University of Birmingham, for the bacteriological examination and cultivation of material removed from the sinuses.

II. Note by Dr. Stanley Barnes.

The research which Mr. Yates has carried through so successfully and recorded above is of vast interest to those of us who are concerned with the paths of infection to the central nervous system. More particularly it has been puzzling to determine how the various facts which are known with regard to encephalitis lethargica can be assimilated into a reasonable theory which will explain the path of infection in this disease. It will be remembered that Levaditi found that the mucous secretions from the mouth in cases of encephalitis were often pathogenic, whilst, as a rule, the salivary duct secretions were not so; again, it has been pointed out many times that certain individuals are carriers of the filter-passing organism, but have themselves shown no sign of the disease. Another fact which must be coördinated with the theory in order that the latter may be accepted is the close association with the epidemic of influenza which started in 1917.

Post-Influenzal Rhinitis as a Precursor of Encephalitis.

Now, it has to be remembered that the latter has been associated throughout its course with several types of the catarrhal group of micro-organisms, and that many cases of encephalitis whose nasal secretions have been examined have been found to be carriers of one or other of this group of bacteria. It is thus probable that after an attack of the severe type of influenza which has occurred within recent years, a certain number of people have suffered from chronic nasal disease of the type which Mr. Yates has been describing; and if these cases of post-influenzal rhinitis had been thoroughly examined, it would be found that one or more of their accessory sinuses were inflamed in accordance with type 4 as described by Mr. Yates. It is clear from his researches that certain toxins and chemical substances, such as indigo-carmine, can pass through the mucous membrane in this condition, whereas the normal mucous membrane of the sinuses is capable of preventing the access of any organism or toxin. It is thus probable that the filter-passing organism of encephalitis when absorbed into the nasal cavity of a normal individual gives rise to no symptom, but when it gains lodgment in the nose of a sufferer from type 4 sinusitis it may pass through the mucous membrane and be absorbed into the deeper tissues. This theory would thus account for the absence of nervous symptoms in those who show the presence of the organism in their naso-pharyngeal secretions, and for the great difficulty which has been experienced in tracing the infection from individual to individual; for it is clear that the rule would be that there should be far more carriers than sufferers, seeing that the organism would be spread by coughing or sneezing and be air-borne, and would only give rise to signs of encephalitis in those who also suffered from the most severe or fourth degree of sinusitis.

Path of Infection.

As to the path by which the organism reaches the central nervous system from the sinuses, it is more than likely that it does not pass by the blood-stream, but does pass by the peri-neural lymphatics along the branches of the first division of the fifth nerve and so reaches the brain. If this is correct it would also explain why so many of the cases have shown evidence of damage to the mesencephalon and pons Varolii, seeing that the ascending root of the fifth nerve is likely to carry the infection close to the ocular nuclei and the mesencephalic structures.

It has been impossible locally to confirm this theory of the mode of infectivity in encephalitis, but it fits in with so many of the observed facts that I feel certain that this is the mode of infection. I would suggest that those who have an opportunity should not only investigate the condition of the various sinuses in cases of death from encephalitis, but should also attempt to trace the organism in the first division of the fifth nerve and the corresponding portion of the Gasserian ganglion on the same side as any sinus lesion. It is possible that the olfactory nerves also act as channels for the absorption of the virus in some instances, and the olfactory bulbs might with advantage be investigated in the same way as the Gasserian ganglion.

It should be remembered in this connexion that the toxin of tetanus has been proved to be carried to the central nervous system from the peripheral focus along the nerve sheaths, so that there is every reason to believe that other organisms may give rise to infection in the same way.

Arguments on similar lines may be applied to the absorption of micro-organisms from the nasal sinuses in cerebro-spinal fever. The work of Orr and Rows showed experimentally that cocci tended to track along the spinal roots centripetally to the cord and give rise to meningitis or to myelitis. Given the original damage to the nasal mucous membrane, which is characteristic of type 4 sinusitis, such a process is likely to occur in cases where nasal infection by the meningococcus is superadded; and a tracking along nerve sheaths (twigs of the first division of the trigeminal, or branches of the olfactory) is theoretically more likely to be the path of infection than an emissory vein.

In a recent communication Behr has shown that it is likely that the infection in certain cases of disseminated sclerosis commences in the posterior ethmoidal sinuses and passes from them to the optic nerves. Here is another instance in which it is possible that a preliminary damage of the type described by Mr. Yates as type 4 sinusitis is necessary before the infective agent can pass through into the nervous system. It is realised that at this stage no decision can be reached as to the exact pathology of disseminated sclerosis beyond the fact, which is fairly established, that there is an invasion of the nervous system by some parasite; nevertheless, the large number of cases in which preliminary histories of nasal catarrh are almost the only predisposing factor in otherwise healthy young adults who develop disseminated sclerosis is of itself a strong reason for believing that there must be some causal connexion between the two.

Summary.

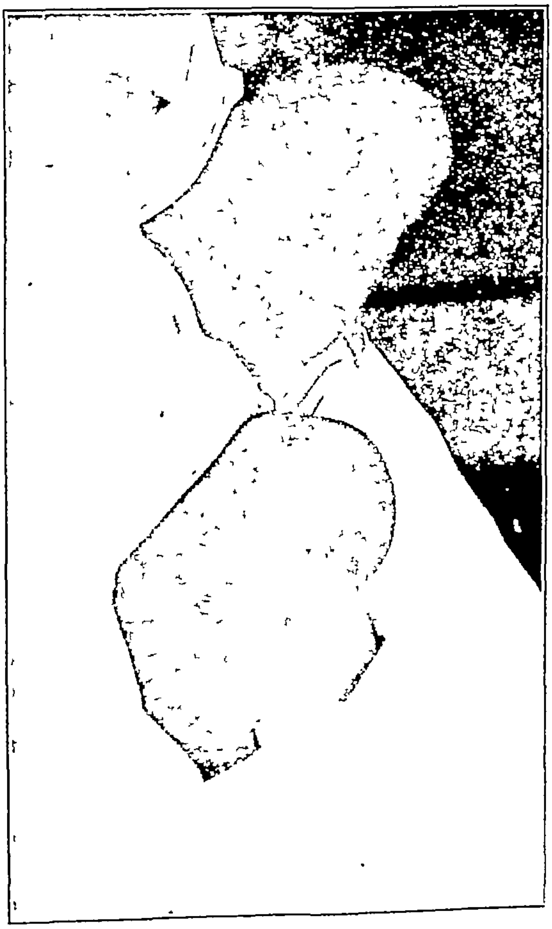
It is thus suggested that the infection in encephalitis (and possibly other central nervous infections) is a symbiotic process; that in the first place the nasal mucous membrane is damaged by one of the catarrhal group of organisms, and that subsequently the virus of encephalitis is inhaled, passes through the damaged mucous membrane, and is absorbed into the brain via the peri-neural lymphatics.

A CASE OF
BILATERAL PREPATELLAR BURSÆ.

By A. TREVOR JONES, M.B., B.S. Lond.,
LATE HOUSE SURGEON, HARROGATE INFIRMARY.

The following case of bilateral prepatellar bursæ presents some unusual and interesting features.

The patient, aged 54 years, was a charwoman who had done a considerable amount of work on her knees for the last 35 years, sometimes doing five hours' continuous work in that position. The right bursal swelling had been present for ten years and the left for six, increasing in size very gradually. They had never caused her much inconvenience, and she only had pain for about ten minutes after starting to kneel; when this had passed away she could kneel for hours without discomfort. When the bursæ were small she used to kneel on them with the anterior surface touching the floor, but latterly they projected so that the inferior surface came into contact with the floor. The skin covering this surface became abraded and septic, and she sought medical attention on this account. There was no limitation of movement at the knee-joints and the patient could move quite briskly. She had some difficulty in stooping and bending from the waist. The right bursa projected about 3–4 inches. It was hard and no fluctuation could be obtained. It was intimately connected with the patella and could only be moved from side to side with that bone. The left projected 3 inches; it was softer than the right, and fluctuant. It also could only be moved with the patella. The skin was abraded over the inferior surface. An idea of the shape and size of the bursæ may be obtained from the accompanying photograph.



Bilateral prepatellar bursæ.

The bursæ were removed by transverse incisions across the joints, the flaps of skin in the left being so arranged that the septic portion was removed. The bursæ were intimately connected with the underlying fascia, with which the fibrous tissue of their walls was continuous. This had to be divided. The wounds healed by first intention.

After removal the size of the right was 7 cm. long, 7·5 cm. deep, and 9 cm. across. The left was 7·5 cm. long, 7 cm. deep, and 6·5 cm. across. On section the cavity in the right was found to be 4 cm. in diameter, the rest of the swelling consisting of extremely hard and avascular fibrous tissue. The cavity contained some blood-tinged serous fluid and was intersected by thin fibrous trabeculæ. Its walls were ragged and breaking down, and there was no sign of serous membrane to be seen. The cavity in the left was larger than that in the right (5·5 cm. across), and occupied a deeper position. The walls were also ragged in places and similar trabeculæ intersected the cavity. The fibrous tissue was not so thick nor so dense. The skin over the summits of the bursæ was fairly thick, varying from about 0·25 to 0·5 cm. A microscopical section showed that the walls consisted entirely of closely-packed fibrous tissue with very few blood-vessels.

It is noteworthy that the older and larger of the two bursæ was the right. The cavity was smaller, the fibrous tissue thicker and denser on that side. The patient was right-handed and stated she always realised putting more strain on the right knee when scrubbing.

I am indebted to Mr. C. D'Oyly Grange for permission to publish the case.

Reviews and Notices of Books.

Psychology of the Pre-School Child.
By Bird T. Baldwin, Ph.D., Research Professor in Educational Psychology and Director of the Child Welfare Research Station in the State University of Iowa; and Lorle I. Stecher, Ph.D., Research Assistant Professor in the same station. London and New York: D. Appleton and Co. 1924. Pp. 305. 8s. 6d.

This book describes a systematic attempt to do for the mentality of the child of pre-school age what the child welfare movement is doing for his physical development. It necessarily contains accounts of investigations rather than practical educational suggestions, which can only follow upon further inquiries on these or similar lines. The results of a series of day-to-day observations and measurements from a large and varied selection of tests extending over a period of one to three years on a group of 105 children are recorded in detail. The children ranged from 2 to 6 years of age and were in attendance at the Child Welfare Research Station, Iowa. Certain physical measurements of growth were made, including roentgenograms of the carpal bones and the teeth, but the work was predominantly psychological. The tests employed included, besides scales of general intelligence, numerous measures of motor control and coordination, and certain practical perceptual and associational tests, such as the Knox cubes, Goddard's adaptation test, and Healy's picture-completion Many are already well known, but results of trials on so young children have not been often recorded; other new tests were also applied, some of which showed considerable originality. The experiments to record the development of the senses of number, time, rhythm, and design are particularly valuable, both as tests and as means of education. The authors have throughout endeavoured to combine educational value with their investigations, and they maintain that it is a mistake to allow a child's mind to grow naturally. To deprive a little child of the instruction it craves is, they believe, to withhold the conditions of normal mental development. Definite conclusions regarding early mental development are not justified from observation of so small a number of cases, and in any case results of the application of tests made under artificial conditions require to be supplemented by the daily study of children under natural conditions by a trained observer, on the lines set out by Sully.

The book, while primarily of interest to teachers of nursery schools, deserves the attention of child welfare medical officers who wish to study the mentality as well as the physique of their subjects.

LECTURES ON DYSPEPSIA.

By ROBERT HUTCHISON, M.D., F.R.C.P., Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street. London: Edward Arnold and Co. 1925. Pp. 176. 5s.

THE writings of Dr. Robert Hutchison always possess a charm which makes them especially welcome; moreover, the author's long experience and critical outlook equip him for the difficult task which he has undertaken in the present volume. The lectures are not all equally informative. The essay on the Diagnostic Significance of Abdominal Pain and on the Chronic Abdomen, and the sections dealing with Organic Diseases, such as peptic ulcer and carcinoma of the stomach, are excellent, but, when Dr. Hutchison reaches the crux of the problem of "dyspepsia"—namely, what, in Lecture VII., he terms the functional dyspepsias—his conclusions are so vague that we doubt whether new light is shed on the indefinite and numerous group of sufferers there dealt with. Can any writer do more at the present day? We doubt it, but Dr. Hutchison has specifically set out to lecture to students on "dyspepsia" and, if this symptom is to be retained in a prominent position in medical nomenclature, it seems desirable to obtain more justification for its use than is here given.

Any disappointment which we may feel on this score is enhanced by our admiration for Dr. Hutchison's concluding lecture on the Chronic Abdomen. This address deserves recognition as a classic, but the tragic pictures described so brilliantly will only disappear when the profession has more insight into the obscure beginnings which are dealt with in earlier chapters.

INFECTION, IMMUNITY, AND INFLAMMATION.

By FRASER B. GURD, B.A., M.D., C.M., Lecturer in Applied Immunology and in Surgery, McGill University. London: Henry Kimpton. 1924. Pp. 329. 25s.

THE author believes that sufficient data regarding the phenomenon of tissue hypersensitiveness and its companion state, tolerance, have been accumulated to justify their application in medicine and surgery. He gives a clear and readable account of the phenomena of immunology which should appeal to the practising physician and surgeon for whom the book is written. If at times his explanation of certain of the tissue reactions to infection seems unduly simple and dogmatic, this is probably a fault on the right side. It may be doubted whether our knowledge of immunology is so advanced that treatment on these lines can be said to have left the experimental stage. But this book is at least a worthy attempt to introduce scientific conceptions into therapeutics, and so deserves attention.

HISTO-BIOLOGY OF THE SKIN.

Lectures on the Histo-Biology of the Skin, and Its Diseases. By Dr. JOSEPH KYRLE, a.o. Professor of Dermatology and Syphilology at the University of Vienna. Vol. I. Vienna and Berlin: Julius Springer. 1925. With 222 mostly coloured illustrations. Pp. 345.

THOSE who have had an opportunity of attending Prof. Kyrle's histological lectures will rejoice at the incorporation of 35 of them in a readable volume, admirably and profusely illustrated by a well-known artist. In the preface it is modestly suggested that these lectures may be helpful to such students as may require a general knowledge of cutaneous histology, but dermatologists will agree that the work should be placed in a much higher category than that claimed for it by the author. In his lectures on normal histology Prof. Kyrle has a happy knack of combining a detailed description of form, with an interesting, if somewhat dogmatic, dissertation on the associated physiological functions of the various structures in the skin. This is a new and agreeable departure which should do much to obviate the lack of enthusiasm generally felt for the study of a rather prosaic subject. The volume is divided into six unequal parts. They include: (1) A description of the histology of the normal skin, (2) pigment anomalies, (3) atrophic and (4) hypertrophic disturbances, (5) mycelial infections, (6) effects of parasitic invasion. There is a short index of authors' names, and a good subject-index. The illustrations are among the best and most accurate that have ever appeared in a work on cutaneous histology, and in virtue of their faithful reproduction of important features, the number and variety of stains employed, and the careful selection of the material for biopsy, may long defy the emulation of other histologists in this field.

Dermatologists will welcome this fresh proof of Prof. Kyrle's ability and will look forward to the appearance of subsequent volumes.

HEALTH AND PSYCHOLOGY OF THE CHILD.

Edited by E. SLOAN CHESSER, M.D. London: Wm. Heinemann. 1925. Pp. 302. 7s. 6d.

DR. Sloan Chesser may be congratulated on having provided a book of real and big interest. Uniformity of outlook is not to be expected in a work of this kind, and it must be admitted that the majority of readers will hardly synthesise the material presented to them into a working scheme of child management, while some may be rather bewildered by the diversity of the factors which are represented as conditioning the development of the child. But as a collection of essays written from widely different points of view by authors who are well qualified to represent them, it should achieve considerable success, and will stimulate the interest of almost every reader in some aspect of the subject which will be new to him. The variety of the subject-matter may be indicated by mentioning a few chapters: Dr. E. Pritchard deals with the psychology of infancy and Dr. H. C. Cameron with want of appetite in children; the development of self-consciousness is discussed by Dr. J. A. Hadfield, the influence of endocrines and vitamins by Dr. Leonard Williams, and delinquency in children by Dr. A. F. Tredgold.

The book is clearly and attractively written, and may be recommended to all who are interested in problems of childhood.

ORGANIC CHEMICAL ANALYSIS.

A Student's Manual of Organic Chemical Analysis, Qualitative and Quantitative. By JOCELYN FIELD THORPE, C.B.E., F.R.S.; and MARTHA ANNIE WHITELEY, O.B.E., D.Sc. London: Longmans, Green and Co. 1925. With diagrams. Pp. 250. 9s.

THIS book is divided into eight sections, the first two of which are devoted to the detection of elements in organic compounds and the methods of purification of organic compounds before analysis. Then follows a section on the ultimate analysis of organic compounds in which the historical development of the subject is traced by a description of the original methods devised by the earlier workers in this field of organic chemistry. Full particulars are given for carrying out the experiments and references are quoted, so that the student is encouraged to look up original papers for himself. The fifth section, which is the longest, will also be found to be the most generally useful, containing as it does the methods of detection and estimation of all the commoner radicles met with in organic compounds, together with a number of practical applications of these methods to the estimation of some compounds of technical importance such as methyl alcohol and formaldehyde. The sixth section contains some practical hints for the systematic examination of complex organic compounds, and there is also an appendix dealing with the methods of micro-analysis. The book forms a useful addition to the literature of the subject.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE. May, 1925.—The principal article is by E. L. Collis, and deals with the coal-miner, his health, diseases, and general welfare. It is of some interest at the present moment when the mining industry is engaging much attention. The habits of the miner with regard to food, drink, and baths are considered; his methods at work; his occupational diseases, nystagmus, beat-knee, beat-hand, and beat-elbow; his tendency to accidents; his exposure to dust—are all summarised; his social environment in regard to welfare schemes and fertility is discussed, and the relation of unrest on the different coal-fields to the prevailing mortality is pointed out. The conclusion is arrived at that the mind of the miner is affected by such things as those dealt with and expresses itself in a tendency to strike.——June, 1925. The results of two years' ophthalmology in an American manufacturing plant are set forth by H. P. Davidson, who, after 4000 consecutive examinations, found 28·5 per cent. of the men with normal vision in both eyes and 38·9 per cent. with normal vision with lenses; but among the rest there was an appalling number of amblyopias, maldevelopments, and old injuries. The findings are carefully tabulated. The writer is emphatic on the need of education to induce men to wear goggles to prevent injuries and to seek advice for their children.—The health hazards of garages are pointed out by G. M. Burnham to be considerable. Acute and subacute poisoning from carbon monoxide in exhaust gases is an ever-lurking danger. The tendency to enrich fuels with cracked petroleum, coal distillate, and even lead compounds is adding further danger. Heavy vapour from spilt gasoline may drift into a pit where a man is working or poison him if the garage be closed. The writer calls for thorough investigation to establish the damage to health resulting and to determine the best preventive measures.—An interesting description is given by P. Drinker and R. M. Thomson of a portable alternating current precipitator for determining dust, fumes, and smokes present in air. The apparatus, which is illustrated, weighs 13 lb., and samples for microscopic study can be obtained.—The need for determining the zinc content of various foods, animal tissues and bone, and excreta, in cases of both normal and abnormal contact with zinc has led R. E. Lutz to develop a method for detecting accurately amounts varying from 0·01 mg. to 0·5 mg. by the action of zinc salts on urobilin. The method is described and discussed critically, with reference to previous work done on the subject.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

FURTHER SITTINGS.

(Continued from p. 1367, June 27th.)

EVIDENCE OF L.C.C. MENTAL HOSPITALS COMMITTEE.

AT the resumed meeting of the Commission on July 10th, the Hon. W. Sidney, J.P., and Mrs. Dunn Gardner, J.P. (chairman and vice-chairman of the L.C.C. Mental Hospitals Committee), gave evidence and stated that their view—supported by the Council—was that provision for temporary treatment without certification should fall on the same authority as that responsible for the established mental hospitals. Also, they thought that any legislation for early treatment of mental cases should allow patients who did not possess volition to be treated, as well as really voluntary patients. The Council considered that for compulsory detention two medical certificates—one from a specially approved general practitioner—should be required. The number of medical officers treating mental cases under the Council had of recent years been considerably increased. Hospitals with 2000 patients or over were allowed eight assistant medical officers. The Council did all they could to induce young medical officers to obtain the diploma in psychological medicine, and had arranged courses of lectures at the Maudsley Hospital for post-graduate students in this regard. The eighth course was now being delivered. Leave was also granted to attend a three-months course at the same hospital. Here was the chief pathological laboratory in connexion with the London County mental hospitals. The director of this laboratory was Dr. F. L. Golla, who followed Sir Frederick Mott, the latter now occupying the chair of mental pathology at Birmingham University. A properly equipped laboratory was provided at each mental hospital under the Council, and Dr. Golla conducted a periodic inspection of these laboratories, and reported on the work being done in them.

With regard to the nurses in the Council's mental hospitals, every inducement was held out to them to gain the mental nursing diploma. Recognising the onerous and somewhat distasteful work these nurses were sometimes called upon to do, and in order to make the staff as contented with their conditions as possible, the Council had shortened the hours and increased the rate of remuneration paid. It was difficult to secure a sufficient number of suitable women for this nursing work.

ASSOCIATION OF MUNICIPAL CORPORATIONS.

On the following day, July 11th, evidence on behalf of the Association of Municipal Corporations was given by Sir Lewis Beard, the town clerk of Blackburn. He said the average yearly increase in the number of patients who needed treatment in mental hospitals in England and Wales for the years 1920 to 1923 was 3565, and his Association's suggestion—until building was a less burdensome matter—was that use should be made of vacant institutions under the control of the Poor-law guardians. These, he thought, could be used for the more chronic type of case, and this would release space in the usual mental hospitals for acute cases in which treatment was likely to bring results. He had in mind the ordinary residential wards of the Poor-law institutions. His Association, he said, supported the Mental Treatment Bill, and their view was that it ought to be made possible to treat incipient cases without first having them certified. His individual opinion, also, was that it would be well if local authorities were to undertake the instruction of the public as to the general nature of mental disorder and the need for it to be treated at quite an early stage. A further advantage of this would be the dissipation of much of the unfounded prejudice in regard to insanity and the methods of treating it.

He had had a good deal of experience as a visitor to asylums, and suggested that committees appointed to do the visiting should be named "mental hospital committee" as he thought the usual name of "visiting committee" conveyed the impression that the inspection was of a perfunctory character, instead of the careful and interested inspection which was needed. He was against the Board of Control being given mandatory powers in place of the present advisory functions, as he wished to preserve to local authorities a good deal of freedom concerning details.

GIFT TO THE NATIONAL ORTHOPÆDIC HOSPITAL.—Mr. Dudley Docker has promised to contribute £5000 towards the £87,500 required by the Royal National Orthopædic Hospital on condition that four others will give a similar amount.

MEMORIAL TO THE LATE DR. WALLACE BEATTY, OF DUBLIN.—*On July 9th a tablet to the memory of the late* Dr. Wallace Beatty was unveiled in the hall of the Adelaide Hospital, with which he was so long connected. In addition to erecting the tablet the committee in charge of the memorial has in its hands a fund from which it is hoped to help nurses and students of the hospital financially embarrassed. The ceremony of unveiling was performed by Dr. Walter Smith, Dr. Beatty's predecessor at the Adelaide Hospital. He referred briefly to Dr. Beatty's fame and skill as a dermatologist, and more especially to his kindness, charity, and character as a man.

Treatment of Diabetes

The action of Insulin is incontestable, but its use is only advisable in severe cases.

PANCREPATINE

(A.F.D.)

is a combination of a Special Extract of the Pancreas with Hepatic Extract, prepared for

Oral Administration Only.

Results claimed:

(1) Reduction of Glycæmia.

(2) Reduction and sometimes total disappearance of glycosuria.

(3) Disappearance of polyphagia and return of normal appetite.

(4) Improvement in general health and mental activity.

Bottles of 100 Dragees, each containing 25 cgm.

PURE OXIDE OF TIN AND TIN METAL

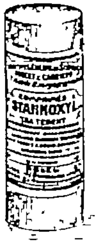
STANNOXYL

Treatment of Staphylococcal Affections.

Acne, Boils, Carbuncles, Styes, etc.

STANNOXYL has been experimentally studied very closely before being used in actual practice. Results of experiments have been given in communications to the Academy of Science, May 15th, 1917; Academy of Medicine; the Hospitals Medical Society; the Society of Surgery; and in articles in *The Lancet*, Jan. 19, 1918, p. 99; and *Journal R.A.M.C.*, May, 1918, p. 515.

> "That Stannoxyl appears to afford a sure and efficient method of general treatment for such staphylococcal infections as furunculosis and acne would seem to be proved, confirming the result already obtained in France by Frouin and his co-workers."—THE LANCET, Jan. 19, 1918.



INTERNAL TREATMENT—STANNOXYL TABLETS, tubes of 80.
EXTERNAL „ — „ LIQUID, GLYCERINE, OINTMENT, ETC.

Full particulars on application.

Telephone: MUSEUM, 4029. *Telegrams:* "AMPSALVAS, LONDON."

THE ANGLO-FRENCH DRUG CO., LTD.,
238a, GRAY'S INN ROAD, LONDON, W.C. 1.

TRADE **‘BYNO’** MARK

HÆMOGLOBIN

The Pre-eminent Hæmatinic

‘Byno’ Hæmoglobin is a unique preparation containing hæmoglobin, proteins and salts of fresh blood, conserved in such a way as to avoid any chemical degradation or physical change, and combined with ‘Bynin’ Liquid Malt, itself an active digestive agent and a valuable nutrient.

It has been shown conclusively that hæmoglobin is distinctly superior to the inorganic salts and other compounds of iron in combating anæmia. Hæmoglobin—the form in which iron is present in the blood—is readily assimilated; it does not give rise to digestive or other functional disturbances.

‘Byno’ Hæmoglobin is specially indicated in the anæmias, in debility due to malnutrition, in menstrual disorders and in convalescence.

Samples and special literature will be sent on application, to members of the Medical Profession.

THE LANCET.

LONDON: SATURDAY, JULY 18, 1925.

TOWARDS THE SOLUTION OF THE CANCER PROBLEM.

The publication in The Lancet to-day of the paper by Dr. W. E. Gye on "The Ætiology of Malignant New Growths," marks an event in the history of medicine For these observations may, we believe, represent a solution of the central problem of cancer. His carefully controlled experimental evidence leads to certain fundamental conclusions which may be briefly summarised as follows:—

1. All malignant new growths contain an ultramicroscopic virus—or group of viruses—which can be cultivated. This applies to the carcinomata and sarcomata of fowl, mice, rats, dogs, and man. The virus resides probably within the cells of the neoplasms.

2. The virus alone, washed free from all adherent material, does not produce a tumour when injected, and does not even produce a visible lesion.

3. But when injected together with virus-free extracts of tumours the virus produces a malignant new growth. The extracts contain, therefore, a substance called by Dr. Gye the "specific factor," which enables the virus to attack the cells of the injected animal so as to transform them into cancer cells.

4. There is no species specificity so far as the virus is concerned, for tumours can be obtained in one species of animals with the virus obtained from the tumour of another species.

5. The "specific factor" shows a very strict specificity of species. Thus in order to produce a malignant new growth in a mouse it is necessary to use the specific factor from a mouse tumour, while the specific factor of a chicken tumour is ineffective.

6. There is probably also a strict specificity of tissue for the specific factor. So far only sarcomata have been obtained, and these only with a mixture of virus and the specific factor from sarcomata, not from carcinomata.

The existence of a virus is not merely postulated from the effects of a culture supposed to contain it, as has hitherto been the case. The paper by Mr. J. E. Barnard on "The Microscopical Examination of Filterable Viruses" follows Dr. Gye's communication, and in this he has applied the optical methods elaborated by him for the study of the organisms of bovine pleuro-pneumonia, the largest of the known filter-passing viruses, to the study of the cancer viruses cultured by Dr. Gye, and shows that he has succeeded in rendering the cancer virus visible and even in photographing it. This is in itself a great achievement. The results of Mr. Barnard's observation so closely correspond with the experimental results obtained by Dr. Gye that the existence of a living cancer virus would appear to be established. The reasons for this broad opinion follow.

In order to make clearer the relationship existing between the virus and the specific factor, definite examples may be given. We will call the virus obtained from a mouse tumour "mouse virus," from a human tumour "human virus," and so on. Similarly we will call the "specific substance" obtained from a mouse carcinoma "mouse carcinoma specific," from a human carcinoma "human carcinoma specific," from a fowl sarcoma "fowl sarcoma specific," and so on. Then the following relationships have been established experimentally after injection:—

(*a*) Any virus alone from any neoplasm into any animal: no effect.

(*b*) Any specific from any neoplasm into any animal: no effect.

(*c*) Mouse carcinoma virus + fowl sarcoma specific: (1) Injected into mice—no effect; (2) injected into fowls—sarcoma.

(*d*) Human carcinoma virus + fowl sarcoma specific injected: Into mice—nothing; into fowls—sarcoma.

It follows, therefore, that the type of malignant new growth that is produced depends not upon the virus, but upon the specific substance. There are, therefore, two factors concerned in the ætiology of cancer: (1) A living virus—the extrinsic factor; and (2) a chemical substance produced by the cells—the intrinsic factor.

The "germ theory" of cancer is, of course, not a new one. It has often been advanced and has as often been rejected. It has been pointed out in the past, and quite truly, that it does not explain cancer. Recently an American authority on cancer has gone so far as to make the categorical statement: "There are many things which we do not know about cancer to-day, but there is one thing that we do know and that is that it is not of germ origin." That is not merely the opinion of a single individual, but it represents the view of almost every pathologist of repute. That view is not merely justified by the consideration that in the past no one has ever isolated an organism which when injected would produce with certainty a typical malignant new growth. As we shall see it is true even to-day in the light of Dr. Gye's work to say that the presence of an organism *by itself* cannot account for the fundamental features of cancer, and if the statement quoted above had been formulated in this way no exception could be taken to it. The position may be stated more generally by saying that cancer cannot be explained by postulating an entirely extrinsic origin.

Why, then, do we accept Dr. Gye's observations as a solution of the cancer problem? In order to appreciate the full significance of this work it is necessary to review briefly the present state of the cancer problem. A brief historical summary of the development of cancer research shows both the peculiar dilemma with which every attempt at explaining cancer was faced and the brilliant way in which Dr. Gye has dealt with it. Up to the beginning of this century the investigation of cancer was entirely in the hands of morbid anatomists and morbid histologists. They described the morphological appearances of the different tumours found in man and classified them; they made the fundamental distinction between neoplasms derived from epithelial cells and from connective tissue cells; they showed that each individual tumour had individual morphological features, and that these features were retained by the metastatic deposits; they correlated different degrees of malignancy with morphological differences. From the point of view of treatment the most important contribution was the work of Ribbert and of Butlin.

The former from a study of early carcinomata showed that cancer in its inception was a local disease. BUTLIN, applying this conclusion to surgical treatment, emphasised the importance of operative removal at the very earliest stage of cancer and demonstrated in this way that cancer, if attacked sufficiently early, was a curable disease.

There was also a considerable output of theories concerning cancer. Every possible—and impossible—explanation that human ingenuity could devise was put forward. Fortunately it is not necessary to review these various theories. It is sufficient to say that they have not assisted in the investigation of cancer; it may be said that these guesses at the truth have been of as little value to cancer research as racing tips are to the breeding of horses.

The exclusive occupation with cancer as it occurs in man led, however, to one curious result: it gave rise to the belief that cancer was essentially a disease of man. When in 1888 HANAU described a tumour in a rat and successfully transplanted it into other rats, this important observation was allowed to pass unnoticed. The same fate befell the similar observations which MORAU made soon afterwards. If we consult the standard work of the time, BORST's big volume, published in 1902 and entitled "Die Lehre von den Geschwülsten," no reference at all is to be found to the tumours of animals, although the occurrence of such tumours was well known to veterinary pathologists who had published descriptions in the literature. When, therefore, in 1902 Prof. JENSEN, of Copenhagen, recorded the successful transplantation of a mouse carcinoma into other mice after previous attempts with three other carcinomata had failed, his work did not attract much attention and would probably have shared the fate of HANAU'S and MORAU'S but for a fortunate coincidence. In 1902 the Imperial Cancer Research Fund had come into existence. The late Dr. E. F. BASHFORD, who had been placed in charge of the work of the Fund and who in his preliminary scheme of investigation had emphasised the importance of placing cancer research on an experimental basis, recognised the value of JENSEN'S work and devoted all the resources of the new institution to make the study of cancer one of experimental and comparative pathology. Together with Dr. J. A. MURRAY, he showed that the phenomenon of cancer was common to the whole vertebrate kingdom. By studying the pathology of JENSEN'S tumour and other tumours in mice, these two workers showed that these tumours corresponded in every respect to cancer in man. They confirmed JENSEN'S conclusion that in the process of transplantation the transplanted tumour grew from the cells of the minute piece of tumour that had been introduced by the needle and not by a transformation of the cells of the new host, who only provided the stroma necessary to nourish the cancer cells. This meant that the experimental transmission of a tumour from one animal to another was not a process of infection but one of true transplantation. Every spontaneous tumour in mice that was investigated was shown to possess a definite biological individuality which manifested itself not only by its morphological appearance, but also by such features as its rate of growth, its tendency to necrosis or spontaneous absorption, its power to elicit a specific stroma reaction. What is more, every tumour retained this biological individuality through many years of transplantation, and there was no evidence of convergence to a common type. Although a successful transplantation, of a mouse tumour into other mice was comparatively easy, it was found impossible to transplant a mouse tumour into animals of a different species. This strict species specificity explained the negative results which had attended previous attempts, such as those of SHATTOCK and BALLANCE, to transplant a human cancer into animals. The transplantation of a cancer from one mouse to another was found to be dependent upon the life of the transplanted cancer cells. Inoculation of extracts of tumours or dried tumour material failed to produce new growths, and similarly negative results were obtained when the tumour cells had been kept in an incubator sufficiently long to impair their vitality.

Another important conclusion which followed from these observations was that when a cancer arises in an organism it arises there *de novo* as a result of a change in the cells of that animal and not by the introduction of a cell already cancerous from another animal; each case of cancer was, so to speak, an individual disease. Results such as these could not be accounted for readily on the basis of a germ theory pure and simple. We should have to assume a highly specific virus not only for each species of animal but even for each individual case of cancer. As if to emphasise this conclusion there was on record a tumour of the dog which, though indistinguishable from a typical sarcoma in its morphological appearance and its property to metastasise freely, clearly showed from its clinical history that it did not arise *de novo* but was transmitted during coitus from the vagina to the penis and vice versa. This venereal tumour had been the subject of careful experimental study by BELLINGHAM SMITH and J. W. WASHBOURN in 1897. They clearly recognised the infective nature of the disease—a conclusion which was confirmed by BASHFORD and MURRAY, who contrasted it with the tumours of mice, and by most subsequent observers. It was accordingly called either an infective granuloma or an infective sarcoma, even though no infective agent could be isolated. It has never been clearly established whether the tumour was transmitted during coitus by a process of infection or by the rubbing in of living cells from a tumour on the penis into the vagina, and conversely from a tumour in the vagina into the penis. But whatever the process was by which it was transmitted, it was clear that it did not arise *de novo* in each animal in the same way as most neoplasms arise. Here, then, was the first clear evidence that tumours existed which could not be distinguished morphologically from a typical sarcoma but which had apparently quite a different ætiology.

Other evidence soon followed, but the attempt to place cancer research on an experimental basis by studying it in animals met at first with violent opposition by many pathologists. They maintained that cancer in mice was a disease quite different from cancer in man. But by the persistent accumulation of facts, BASHFORD and his collaborators carried the day. Cancer research institutes were established all over the world where the various aspects of the cancer problem were being studied experimentally in animals.

Then a really extraordinary observation was made in 1911 by Dr. PEYTON ROUS, of the Rockefeller Institute. In a fowl he found a sarcoma which could be transmitted to other chickens not merely by the introduction of the living tumour cells, but also by an extract which had been rendered cell-free by filtration through a Berkefeld filter. The same successful result could be obtained with the dead tumour material which had been dried and kept for some time. Pursuing this line of investigation he found two other sarcomata in fowls showing the same properties. But not all tumours of fowls behaved in this way:

many of them, like the tumours of mice, failed to yield tumours with the cell free filtrate or the desiccated tumour. Here, then, was convincing experimental evidence that in certain cases a tumour could be produced *de novo* either by a living virus or by a chemical agent. And the most perplexing feature of these extraordinary observations was this. Each of the three sarcomata showed a very distinctive biological individuality in their morphological appearance—one of them, for instance, being an osteo-chondrosarcoma. Tumours which were produced by the cell free filtrate or by the dead dried tumour material retained this biological individuality in the same way as did the mouse tumours which depended for their propagation on the living tumour cell! The most obvious explanation appeared to be that these tumours were due to a virus. But if that was so, why did the virus reproduce the biological individuality of each tumour? There seemed to be no answer to that question, and PEYTON ROUS, after having contributed one of the most important and disturbing observations, retired, baffled, from cancer research, as EHRLICH had done before him.

The next advance in cancer research was made by FIBIGER. He produced cancer of the stomach in rats by allowing a nematode to develop in the wall of the stomach. Once the carcinoma had developed it could be propagated in other rats in the usual way by the transplantation of the living tumour cells so that the presence of the nematode was not an essential factor in the growth of the tumour once it had been induced. Similarly BULLOCK and CURTIS, in the Crocker Institute in New York, produced sarcomata in the liver of rats by infecting the rats with the eggs of *Tænia crassicollis*. The sarcomata then developed in the walls of the cysticercus cysts. YAMAGIWA and ISHIKAWA, interpreting these results as being due to chronic irritation, produced epitheliomata in rabbits and mice by the prolonged painting of the skin with tar.

This line of investigation on the experimental production of cancer again offered no evidence in favour of the germ theory of cancer. On the contrary, the multiplicity of agents capable of inducing cancer, the long latent period in tar cancer, the cellular hyperplasia preceding the cancerous change had to be interpreted as arguments against an extrinsic origin and in favour of an intrinsic origin of cancer. Now that we know the solution, it is fascinating to retrace the history of experimental cancer research and to see how the objective, unbiassed collection of observations bearing on cancer in animals had led up to this dilemma: there was a large body of observations which could not be accounted for satisfactorily by postulating an organism as the cause of cancer. They indicated rather that the cancerous change was associated with a change in the metabolism of the cells, perhaps the production of a substance stimulating growth as indicated by the studies of CARREL, BURROWS, DREW, and others on the cultivating of cells in vitro. On the other hand, there were the tumours described by ROUS and the venereal dog tumour which, though morphologically typical malignant new growths, seemed to have an entirely different ætiology and could be explained most readily by postulating an infective agent. Most workers tried to escape from this maze by setting aside tumours such as those *described by* ROUS as being infective granulomata and by making a sharp distinction between such tumours and true neoplasms. But such a conclusion was merely an attempt to evade the difficulty. As has been stated, the fowl tumours were morphologically and clinically indistinguishable from true neoplasms, and apparently arose *de novo* in each animal, and their infective nature could only be established by experimental methods. How was it possible, then, to decide whether a tumour in man was an infective granuloma of this type or a true neoplasm? It has also been stated that the fowl tumours retained their biological individuality, when they were induced by infection with the cell free filtrate. If it is admitted that a virus can produce a cell proliferation of as definite a biological individuality as a true neoplasm, this feature of true neoplasms ceases to be an argument against the parasitic origin of cancer. CARREL has recently tried to get over this difficulty by denying that the chicken tumours are due to a virus. But the cultivation of a virus by Dr GYE and the success of Mr BARNARD in rendering the virus visible under the microscope renders this view untenable.

Dr GYE's work has solved this dilemma in a manner which is as unexpected as it is convincing. He shows that there is both an extrinsic and an intrinsic factor concerned in the ætiology of cancer. The extrinsic factor is a virus common to all neoplasms. By itself it is incapable of producing a neoplasm. To do that it requires the intrinsic factor—a substance produced by the cells which enables the virus to attack the cells. The virus can be cultivated. The intrinsic factor which so far has been demonstrated only in different tumours is presumably produced by the cells in the course of chronic irritation. The intrinsic factor varies from tissue to tissue and from tumour to tumour. In such tumours as those observed by ROUS it is abundant and very resistant, so that it persists even in an extract made without special precautions; in most other tumours it is present in small amounts and very labile, so that special anaerobic conditions are necessary to preserve it and to demonstrate its existence. This apparently fundamental difference between the ROUS tumours and other tumours is, therefore, merely the manifestation of different degrees of lability of this specific substance. Experimental cancer research has brought to light a number of other facts, the explanation of which has hitherto presented great difficulties. As an instance we may mention the development of sarcomata in the course of the experimental propagation of certain carcinomata as described by EHRLICH, by HAALAND, and by RUSSELL. For all these difficulties Dr GYE's work offers a satisfying solution—a good test of the value of the conception which he has formulated of the ætiology of cancer. As already stated, Dr GYE has succeeded in producing a sarcoma with the virus obtained from a carcinoma. The reverse result has not yet been attained—nor has it ever been observed to occur spontaneously in the course of the experimental propagation of sarcomata.

The work of Dr GYE is the outcome of an investigation on ultramicroscopic viruses instituted by the Medical Research Council. A group of men were appointed to work in different special directions, a member of which, Dr P. P. LAIDLAW, gave invaluable help towards finding the direction in which new researches might most profitably proceed. The Medical Research Council is to be congratulated on having secured the services of Dr GYE and Mr BARNARD, whose successful work has opened up a new chapter in the investigation of disease. We have stated at the outset that we hold Dr GYE's work to be a solution of the central problem of cancer. But it is more than that. Dr GYE has also evolved a technique for cultivating ultramicroscopic viruses and a method of testing for their presence. The observation that a virus by itself is non pathogenic, and requires an accessory substance to produce a specific disease may prove to be of the greatest importance in the further study of the diseases due to these viruses. As Dr. GYE points out, the fact that an organism can be non-pathogenic by itself and manifests its specific pathogenicity only in the presence of some accessory factor is not peculiar to the virus of cancer. A few years ago Dr. CRAMER and Dr. GYE showed that such a phenomenon plays a part in many well-known bacterial infections. Thus the bacteria of gas gangrene by themselves are non-pathogenic. But when certain simple chemical substances are also injected, such as calcium chloride or colloidal silicic acid, a slight but specific lesion is produced in the tissues, and then the specific infection is elicited. and kills the animal. They called this phenomenon "defence rupture" or "kataphylaxis," and pointed out that it applied to other bacterial infections. For instance it holds good for tetanus, and even the course of streptococcal infections may be profoundly altered by the presence of such kataphylactic substances. GYE and KETTLE found this phenomenon to apply also to tuberculous infections. The phenomenon is obviously of considerable importance in determining both the onset and what is vaguely called the virulence of bacterial infections, and it is curious that the importance of these observations was not generally recognised by bacteriologists. But a few months ago Dr. COLEY—the New York surgeon—referred to these observations of CRAMER and GYE in a symposium on cancer, in which he presented the evidence in favour of the parasitic theory of cancer. COLEY suggested that the cancer parasite postulated by him required kataphylaxis to attack the cells so as to produce the cancer lesion—probably the only correct guess that has been made in the voluminous literature of cancer theories.

All this work has cleared the way for a rapid advance in the investigation of cancer along entirely new but clearly defined lines. A host of new questions has arisen, and we have no doubt that by answering them the attack on the cancer problem, which has hitherto baffled medical science, will be brought to a successful conclusion. But there is a far wider outlook than this. The new technical methods now made available will be applicable to research along a whole enormous front. Diseases like measles, small-pox and encephalitis, foot-and-mouth disease and dogs' distemper, may yield their secrets to workers armed with these new weapons.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The thirty-seventh meeting of the Commission was held at the Home Office on July 7th, Lord Lawrence of Kingsgate and later Sir Arthur Worley in the chair. A statement by the Government Actuary dealing with the results of the second valuation of approved societies so far as completed was considered by the Commission. Evidence was submitted by the Stepney Borough Council, represented by Councillor J. H. Barnby, as to the payment of contributions in respect of men casually employed on relief works; by the Sons of Temperance Friendly Society, represented by Mr. T. W. Huntley, as to various matters of approved society administration; by the Association of Poor-law Unions, represented by Mr. R. A. Leach, as to the relations of Poor-law relief to Health Insurance benefits. Thereafter Mr. W. J. Braithwaite gave evidence on the question of the case-value method of remuneration of panel practitioners.—The thirty-eighth meeting of the Commission was held at the Home Office on July 9th, when evidence was submitted on behalf of the National Association of Trade Union Approved Societies by Mr. F. Kershaw, President; Mr. E. Corbey, Secretary; and Mr. G. W. Canter, ex-President of the Association, and Mr. G. P. Blizard covering the whole range of the Health Insurance Scheme, in the need f the var expanding and unifying the arra health services.

CURRENT MEDICAL POLITICS.

THE Representative Meeting of the British Medical Association, now in session at Bath, has before it some important matters of medical policy. A memorandum on Coroners' Law and Death Certification sets out the present anomalies and the difficulties in which the practitioner may be placed. The suggested remedy is one which has already been embodied in a Bill which failed to receive Parliamentary assent two years ago. Therein it was proposed to have two certificate forms, one of which would certify the fact of death or stillbirth and would be signed by the medical practitioner, after viewing the body, within 24 hours after the decease has been notified to him. In addition to this he would forward direct to the registrar a further report as to the cause of death, including any scientific data considered desirable. These reports would be filed in a separate register not open to inspection except by a coroner, a medical officer of health, or superior police officer. Should the certificate of the fact of death not conform with the statutory type the registrar would inform the coroner. The suggested fee for death certification is 5*s*., with a mileage bonus of 2*s*. per mile. No doubt the Representative Meeting is giving attention to the additional burden which this procedure would lay upon the practitioner, and to the question whether it is desirable to withhold from relatives the certified cause of death. The revised report of the Ethical Committee of the Association on the subject of Indirect Methods of Advertising will come up for approval, which carries with it the possibility of issuing a ruling which should guide the practitioner who wishes to publish articles in the lay press without overstepping the bounds of professional liberty. The Special Committee appointed to consider puerperal morbidity and mortality may have some practical contribution to make to another problem which touches the practitioner very closely. The representation of the general practitioner on the General Medical Council will be raised by a Division which is not satisfied with the present status. Prolonged discussion is also probable on the Hospitals Policy of the Association. The principle of contributory schemes and staff funds has been accepted by the Representative Body as a whole, but there is still much difference of opinion as to whether contributions by employers or employees should be regarded as contributions for services rendered or to be rendered. As a result of an instruction given at the Bradford meeting, the Council of the Association is recommending to the Representative Body the establishment of a B.M.A. Charities Committee, the duty of which it would be to direct the attention of members to the need for contributions and to manage a "Charities Trust Fund," the moneys to be distributed among the existing medical benevolent organisations. There is ample matter on the agenda to fill up the four days allotted.

ASCARIS LUMBRICOIDES IN HERTFORDSHIRE.

ASCARIASIS is generally considered to be rare in this country, but in 1923 the attention of the Ministry of Health was drawn to the prevalence of this nematode in the small hamlet of St. Margaret's, Hertfordshire. The village consists of ten cottages with a population of some 60 persons, mostly children, and the source of the infestation appeared to be the water-supply, a pump with disordered valves. The report [1] of the Ministry has now been published by Dr. S. Monckton

---

orts on Public Health Medical Subjects, No. 31. H.M. Office. 6*d*.

Copeman, together with an abstract bibliography of the subject and a tabular review of the symptoms presented by 158 cases of ascariasis under the observation of Dr. F. C. Wellman, of Angola. This is interesting to compare with a similar analysis published some years ago by Mr. W. H. Haw, of Cape Colony.[1] Prof. R. T. Leiper's investigation of ankylostomiasis in Cornish miners revealed a concomitant infection with ascaris in 14·7 per cent., and the general experience of practitioners in Cornwall is that ascariasis is by no means uncommon there. Records at St. Margaret's indicate that the inhabitants have been almost universally affected for several generations and include the story of the infestation of an infant said to be totally breast-fed and of a child who died after vomiting between 60 and 70 worms. It was this fatal case that drew the attention of the medical officer of health to the condition of the hamlet. The endemic prevalence is ascribed to the keeping of pigs and the use of material from the cottage earth-closets and pig-sties as manure. It is being combated by measures of personal hygiene and the repair of the pump. The report includes a survey of the biology and pathology of the worm and a chapter on treatment. Clinically it is agreed that santonin is the most efficient drug, though opinion differs as to whether it acts by killing the worms or merely by lowering their vitality so that they are unable to resist the peristaltic waves. As was pointed out in The Lancet recently,[2] the answer to this problem may lie in an appreciation of the comparative insolubility of santonin.

THE FATAL ILLNESS OF THE EMPEROR FREDERICK: LARYNGOFISSURE THEN AND NOW.

In an obituary notice of the late Mr. Mark Hovell, which appeared in The Lancet last week, the controversy was recalled which raged over the illness and death of the German Crown Prince, later the Emperor Frederick III., for Mr. Hovell was resident at the palace during the latter part of the illness as deputy to Sir Morell Mackenzie, the Prince's chosen adviser. Looked at from the present distance of time the controversy seems to have been largely unnecessary, and to have been due in great measure to jealousy of a foreign colleague in control of an august person. Sir Morell Mackenzie occupied an invidious position, and, although perhaps no one now can know the details of the intrigues which surrounded the conduct of the case, it appears that he was actuated by a single-minded devotion to the medical welfare of his patient. It was a difficult laryngeal case for diagnosis. When Mackenzie first examined the patient in May, 1887, there was a warty swelling over the left vocal process which was suggestive, but not pathognomonic, of cancer. He refused to give an opinion, but removed endolaryngeally on several occasions portions of the growth for microscopical examination. On each occasion Prof. Virchow reported that these specimens, which included the deep parts, showed no evidence of cancer, and he characterised the lesion as a "pachydermia verrucosa." It was not until after the lapse of six months, during which time the Crown Prince attended Queen Victoria's Jubilee and spent some weeks in Britain, that the laryngoscopic appearance became more highly suggestive of malignant disease. In November a subglottic growth was visible on both sides of the larynx; on Feb. 9th, 1888, tracheotomy was performed by Dr. Bramann. The patient died on June 13th, having become Emperor on the death of his father on March 9th. There had been much irritation of the trachea from the tubes, and considerable sloughing of the wound, which Mackenzie believed might have been avoided had his advice on the type of tube been followed. His management of the case appears to have been correct in the light of the results, up to that time, of the treatment of laryngeal cancer by laryngofissure and by laryngectomy. It is possible that, with our present knowledge, a correct diagnosis would have been made in the early stage of the disease, and that a laryngofissure might have been successful, though tumours affecting the vocal process are not particularly favourable objects for operative interference. But with Virchow's reports before him Mackenzie could not have been expected to advocate external operation; when the bilateral subglottic tumours appeared in November nothing but a total laryngectomy would have been possible, and this the patient had already refused. In his book, "Frederick the Noble," Mackenzie gives tables of the results of the various laryngeal operations to that time; 22 cases of laryngofissure had been collected with two successes and an immediate mortality of 6, or 27·2 per cent. The work of Butlin and Semon subsequently developed this operation, so that an intrinsic laryngeal cancer is perhaps as favourable for removal as any malignant growth, and recent statistics show an operative mortality of 6 per cent. and freedom from recurrence for three or more years of 47 per cent. In passing judgment on Mackenzie the accepted teaching of the day must be remembered; indeed, this should always be in our minds when reviewing the procedures of our predecessors.

MECKEL'S DIVERTICULUM.

Of developmental anomalies of the omphalomesenteric duct Meckel's diverticulum is probably the most common. The diverticulum, as such, produces no symptoms, but is liable to cause intestinal obstruction, either by becoming twisted, the torsion involving the bowel from which the diverticulum springs or by snaring a loop of bowel, the apex of the diverticulum being attached, either to the umbilicus congenitally, or to some portion of peritoneum by acquired adhesions. Opinions differ as to whether a healthy Meckel's diverticulum, discovered accidentally during operation, should be removed. Owing to its free opening into the ileum acute inflammation of the diverticulum is rare, but, when it occurs, has a high mortality. Preoperative diagnosis of a Meckel's diverticulum as the cause of an "acute abdomen" is usually impossible. Dr. F. Christopher has recorded [1] a case from St. Luke's Hospital, Chicago, of diverticulitis with perforation. A man, aged 47, had been ill for two weeks with pain in the left lower abdomen, accompanied by fever and rigors. In the left iliac fossa was a very tender elliptical tumour, 4 by 8 in., slightly movable. Leucocytosis 12,800. Cœliotomy revealed some gas and pus, and a tumour composed of adherent omentum enveloping a necrotic diverticulum. The diverticulum was excised and the ileum was sutured. Recovery ensued after a stormy convalescence. On the fifth day a fæcal fistula developed and persisted, though diminishing in size, up to the time of the report, 10 weeks after operation.

RADIUM TREATMENT OF THE UTERUS.

The annual report[2] on the treatment of patients at University College Hospital with the radium allotted by the Medical Research Council contains, in addition to the work of 1924, a summary of the results of the last three and a half years. The hospital has the loan of 872 mg. of radium sulphate which is put up in 11 containers of 0·5 mm. thickness of platinum. Dr. R. T. Lewis refers specially to the treatment of carcinoma of the cervix and menorrhagia. In regard to the former he repeats a warning which has been made elsewhere, and which cannot be too strongly impressed, when he refers to the "stimulant effect of *inadequate* radiation, causing generalised carcinomatosis." More and more is the fact brought out that if the operator has an inadequate amount of radium to produce a specific disease may prove to be of the greatest importance in the further study of the diseases due to these viruses. As Dr. Gye points out, the fact that an organism can be non-pathogenic by itself and manifests its specific pathogenicity only in the presence of some accessory factor is not peculiar to the virus of cancer. A few years ago Dr. Cramer and Dr. Gye showed that such a phenomenon plays a part in many well-known bacterial infections. Thus the bacteria of gas gangrene by themselves are non-pathogenic. But when certain simple chemical substances are also injected, such as calcium chloride or colloidal silicic acid, a slight but specific lesion is produced in the tissues, and then the specific infection is elicited. and kills the animal. They called this phenomenon "defence rupture" or "kataphylaxis," and pointed out that it applied to other bacterial infections. For instance it holds good for tetanus, and even the course of streptococcal infections may be profoundly altered by the presence of such kataphylactic substances. Gye and Kettle found this phenomenon to apply also to tuberculous infections. The phenomenon is obviously of considerable importance in determining both the onset and what is vaguely called the virulence of bacterial infections, and it is curious that the importance of these observations was not generally recognised by bacteriologists. But a few months ago Dr. Coley—the New York surgeon—referred to these observations of Cramer and Gye in a symposium on cancer, in which he presented the evidence in favour of the parasitic theory of cancer. Coley suggested that the cancer parasite postulated by him required kataphylaxis to attack the cells so as to produce the cancer lesion—probably the only correct guess that has been made in the voluminous literature of cancer theories.

Copeman, together with an abstract bibliography of the subject and a tabular review of the symptoms presented by 158 cases of ascariasis under the observation of Dr. F. C. Wellman, of Angola. This is interesting to compare with a similar analysis published some years ago by Mr. W. H. Haw, of Cape Colony.[1] Prof. R. T. Leiper's investigation of ankylostomiasis in Cornish miners revealed a concomitant infection with ascaris in 14·7 per cent., and the general experience of practitioners in Cornwall is that ascariasis is by no means uncommon there. Records at St. Margaret's indicate that the inhabitants have been almost universally affected for several generations and include the story of the infestation of an infant said to be totally breast-fed and of a child who died after vomiting between 60 and 70 worms. It was this fatal case that drew the attention of the medical officer of health to the condition of the hamlet. The endemic prevalence is ascribed to the keeping of pigs and the use of material from the cottage earth-closets and pig-sties as manure. It is being combated by measures of personal hygiene and the repair of the pump. The report includes a survey of the biology and pathology of the worm and a chapter on treatment. Clinically it is agreed that santonin is the most efficient drug, though opinion differs as to whether it acts by killing the worms or merely by lowering their vitality so that they are unable to resist the peristaltic waves. As was pointed out in THE LANCET recently,[2] the answer to this problem may lie in an appreciation of the comparative insolubility of santonin.

THE FATAL ILLNESS OF THE EMPEROR FREDERICK: LARYNGOFISSURE THEN AND NOW.

IN an obituary notice of the late Mr. Mark Hovell, which appeared in THE LANCET last week, the controversy was recalled which raged over the illness and death of the German Crown Prince, later the Emperor Frederick III., for Mr. Hovell was resident at the palace during the latter part of the illness as deputy to Sir Morell Mackenzie, the Prince's chosen adviser. Looked at from the present distance of time the controversy seems to have been largely unnecessary, and to have been due in great measure to jealousy of a foreign colleague in control of an august person. Sir Morell Mackenzie occupied an invidious position, and, although perhaps no one now can know the details of the intrigues which surrounded the conduct of the case, it appears that he was actuated by a single-minded devotion to the medical welfare of his patient. It was a difficult laryngeal case for diagnosis. When Mackenzie first examined the patient in May, 1887, there was a warty swelling over the left vocal process which was suggestive, but not pathognomonic, of cancer. He refused to give an opinion, but removed endolaryngeally on several occasions portions of the growth for microscopical examination. On each occasion Prof. Virchow reported that these specimens, which included the deep parts, showed no evidence of cancer, and he characterised the lesion as a "pachydermia verrucosa." It was not until after the lapse of six months, during which time the Crown Prince attended Queen Victoria's Jubilee and spent some weeks in Britain, that the laryngoscopic appearance became more highly suggestive of malignant disease. In November a subglottic growth was visible on both sides of the larynx; on Feb. 9th, 1888, tracheotomy was performed by Dr. Bramann. The patient died on June 15th, having become Emperor on the death of his father on March 9th. There had been much irritation of the trachea from the tubes, and considerable sloughing of the wound, which Mackenzie believed might have been avoided had his advice on the type of tube been followed. His management of the case appears to have been correct in the light of the results, up to that time, of the treatment of laryngeal cancer by laryngofissure and by laryngectomy. It is possible that, with our present knowledge, a correct diagnosis would have been made in the early stage of the disease, and that a laryngofissure might have been successful, though tumours affecting the vocal process are not particularly favourable objects for operative interference. But with Virchow's reports before him Mackenzie could not have been expected to advocate external operation; when the bilateral subglottic tumours appeared in November nothing but a total laryngectomy would have been possible, and this the patient had already refused. In his book, "Frederick the Noble," Mackenzie gives tables of the results of the various laryngeal operations to that time; 22 cases of laryngofissure had been collected with two successes and an immediate mortality of 6, or 27·2 per cent. The work of Butlin and Semon subsequently developed this operation, so that an intrinsic laryngeal cancer is perhaps as favourable for removal as any malignant growth, and recent statistics show an operative mortality of 0 per cent. and freedom from recurrence for three or more years of 47 per cent. In passing judgment on Mackenzie the accepted teaching of the day must be remembered; indeed, this should always be in our minds when reviewing the procedures of our predecessors.

MECKEL'S DIVERTICULUM.

OF developmental anomalies of the omphalomesenteric duct Meckel's diverticulum is probably the most common. The diverticulum, as such, produces no symptoms, but is liable to cause intestinal obstruction, either by becoming twisted, the torsion involving the bowel from which the diverticulum springs or by snaring a loop of bowel, the apex of the diverticulum being attached, either to the umbilicus congenitally, or to some portion of peritoneum by acquired adhesions. Opinions differ as to whether a healthy Meckel's diverticulum, discovered accidentally during operation, should be removed. Owing to its free opening into the ileum acute inflammation of the diverticulum is rare, but, when it occurs, has a high mortality. Preoperative diagnosis of a Meckel's diverticulum as the cause of an "acute abdomen" is usually impossible. Dr. F. Christopher has recorded[1] a case from St. Luke's Hospital, Chicago, of diverticulitis with perforation. A man, aged 47, had been ill for two weeks with pain in the left lower abdomen, accompanied by fever and rigors. In the left iliac fossa was a very tender elliptical tumour, 4 by 8 in., slightly movable. Leucocytosis 12,800. Cœliotomy revealed some gas and pus, and a tumour composed of adherent omentum enveloping a necrotic diverticulum. The diverticulum was excised and the ileum was sutured. Recovery ensued after a stormy convalescence. On the fifth day a fæcal fistula developed and persisted, though diminishing in size, up to the time of the report, 10 weeks after operation.

RADIUM TREATMENT OF THE UTERUS.

THE annual report[2] on the treatment of patients at University College Hospital with the radium allotted by the Medical Research Council contains, in addition to the work of 1924, a summary of the results of the last three and a half years. The hospital has the loan of 372 mg. of radium sulphate which is put up in 11 containers of 0·5 mm. thickness of platinum. Dr. R. T. Lewis refers specially to the treatment of carcinoma of the cervix and menorrhagia. In regard to the former he repeats a warning which has been made elsewhere, and which cannot be too strongly impressed, when he refers to the "stimulant effect of *inadequate* radiation, causing generalised carcinomatosis." More and more is the fact brought out that if the operator has an inadequate amount of radium salt at his disposal he would do better to leave a case alone than merely to stimulate its growth in place of administering the lethal dose it requires. This specially applies to the inadequate application of radium plates externally for the treatment of carcinoma of the cervix. Dr. Lewis states definitely: "Carcinoma of the cervix adequately treated [with radium] disappears entirely," so that the operator should select for treatment those cases for which his supply of radium is adequate to ensure a prospect of cure or at least retardation of the growth. A valuable section of the report describes the results of treatment by radium of menorrhagia. Out of one group of 32 cases of menopause hæmorrhage treated, 27 are now well in every way. In cases of essential menorrhagia in young women with no signs of pelvic disease encouraging results were procured, and cases were cured after treatment by drugs and curettage had failed. Menorrhagia due to fibroids also responded well to radium. One container holding from 100 to 150 mg. of radium sulphate, placed inside the uterus, reduced large fibroids in a dramatic fashion. At University College Hospital it does not appear to be the practice, as it is at the London Radium Institute, to "crossfire" these fibroids with heavy plating from outside. The whole report makes encouraging reading.

THE BATEMAN APPEAL.

It has been decided to close this Fund, and we thank those of our readers who supported the appeal. The money subscribed has been of the greatest possible service to Dr. Bateman, though the total was less than we had anticipated. The fact that Dr. Bateman had joined no society for coöperative defence influenced many, as we know by their letters, to withhold support, so that it is evident from the outcome of this appeal that the medical profession at large is not prepared to sympathise with those of its members who neglect the obvious precaution of insurance.

SHIPS DISABLED BY DENGUE.

When the sloop, *Antarès*, of the French Navy, was lying at Bahia[1] on Oct. 21st, 1923, 52 of her ship's company of 99 were on the sick-list with dengue. She had in all 71 cases, of whom 43 were sent to hospital. Though only one died the epidemic very seriously impaired the efficiency of the ship, since she was immobilised for two months and 25 men had to be invalided home. She had lain at Dakar, in Senegal, the westmost port of Africa, from Sept. 29th to Oct. 7th, three of the days in dry dock. There was at that time no report of dengue in the colony, only of influenza; mosquitoes were reported "numerous," as is usual at that port. The *Ango*, which had preceded her in the dry dock, had, on arrival at Havre, 40 out of a crew of 56 sick, and in all 55 were received into hospital. The malady was never officially given a name at Havre, but people spoke of paludism, bilious fever, and even of scarlatina, owing to the eruption. *Antarès* left Dakar on Oct. 7th for Bahia, crossed the line on the 11th with the usual celebrations, the ship's company alert and well, though some were bothered with headaches. On the 13th dengue began to show itself quite clearly in 11 cases with frontal headache, suffused eyes, pains in joints without redness or swelling, vomiting, pyrexia, and a fleeting rash; no coryza or sore-throat. Many recovered in two or three days, but there were 25 sick when the ship arrived at Bahia on the 15th. Here the numbers rose rapidly; on the 23rd 35 cases were sent to hospital and others later, where they improved so rapidly that 38 convalescents were returned in the next ten days. The characteristic polymorph leucopenia of dengue was noted in hospital. On Nov. 5th, however, all the five still in hospital, and most of those sent back, relapsed. There were no new men attacked, and those relapsing were far more ill than in the first period, the complications being jaundice, with tenderness and enlargement of the liver, and obstinate constipation. Convalescence was painfully prolonged with great muscular weakness and pyrexia on exertion. No treatment was specially successful, though antipyrin eased pain. Milk caused vomiting, but diluents were readily taken. The disease is ascribed by Dr. Bideau, medical officer of the ship, to a culex, but since he wrote *Aedes argenteus* (*Stegomyia fasciata* in old terminology) is generally incriminated. The insect is called *A. egypti* by Siler and his fellow workers, who give the incubation periods as 11 days in the mosquito and four to ten days in the men attacked. No mosquitoes were seen in the ship after the 10th, but cases appeared between the 13th and 28th, so it is difficult to understand how the infection spread, if there is no infection from man to man, which Dr. Bideau suggests as concurrently possible. In any case this history emphasises the need for mosquito protection of ships' companies in tropical harbours and especially when in dry docks, particularly in ports, like Dakar, known to be specially plagued with mosquitoes. The recent United States investigators of dengue, Siler and his fellow workers[2] insist on the epidemiological relation of dengue and yellow fever, their distribution by a common carrier, and suggest that each is caused by a filterable virus. Dr. I. J. Bideau, Médecin de 1re classe (Surgeon Lieutenant-Comdr.), the medical officer of the ship, had an anxious experience, but his careful report on the outbreak, with its detailed account of cases, have at least won for him the Prix de Médecine Navale for 1925.

PROFESSIONAL X RAY DERMATOSES.

Dr. H. N. Cole, of Cleveland, believes[3] that there are many more cases of radio-dermatitis in professional men, nurses, technicians, and orderlies than is commonly suspected, and it is doubtless with a view to their recognition and treatment before the symptoms have progressed too far that the author has given himself the trouble of collecting the bibliography since 1896 (the X rays were discovered in 1895), describing the symptoms and detailing the pathology and course of Rontgen ray injury as it is seen on the skin. The results are cumulative, but may be postponed for many months or years. In the main they are degenerative, especially in the corium, where sweat and pilosebaceous glands soon tend to disappear. Later the fibrous tissue becomes hyaline, and stains badly with Mallory's phospho-tungstic acid connective tissue stain. Vacuolation and distension of plain muscle-cells may eventually lead to their complete destruction. The most important and far-reaching changes are those noted in the blood-vessels, both arteries and veins. The smaller vessels are obliterated by swelling of the endothelial cells, and thickening of the intima. Elastic fibrils are broken up and absorbed, and may be replaced by fibrous tissue, while the middle coats of arteries become thickened and aid in the general sclerosis of the vascular supply. The newly formed capillaries (telangiectases), so often a striking clinical feature of an old-time X ray injury, are regarded by Dr. Cole as the fruitless attempt of a reparative process to supply a new circulation to avascular tissues, in which as a secondary effect focal necroses are so commonly seen. In the epidermis of an advanced case there are the usual evidences of chronic inflammation, with hyperkeratosis and exfoliation, hyperplasia with acanthosis of the prickle-cell layers, and in serious cases, changes in the basal cell layer (stratum germinativum) with occasional gaps in its continuity. "Perles" of epidermal cells in the upper corium may herald commencing malignant changes. Further study on these lines would certainly be of value in view of the great present-day vogue in radio-diagnosis and therapy.

JUVENILE MORTALITY IN SWINDON.

Dr. Dunstan Brewer, in his latest annual report, states that the real causes of death can only be ascertained by comparing the life-histories of those who die with the life-histories of the survivors, and thus discovering the manner in which adverse factors operate. He is, therefore, compiling the life-histories of Swindon residents who die before reaching adolescence. He gives, however, with the information already at his disposal, an interesting analysis of the deaths of children during 1924.

Neonatal Deaths.—Of the 29 neonatal deaths six were from congenital malformations and theoretically unpreventable, and 17 could not be satisfactorily explained, so that we cannot say whether they were theoretically saveable or not. Of the remaining six, which were satisfactorily explained, four at least were theoretically preventable, three being from congenital syphilis and one from ill-feeding.

Deaths from End of First Month to End of First Year.—These may be divided into those who attended the clinics and whose life-history is known and those about whom information was only obtained after death. It should be explained that the social position of Swindonians is remarkably level, there being few citizens at the top or bottom of the social scale. The so-called residential class is very small and is not fertile. It therefore comes about that 90 per cent. of the children attend the clinics. Among the babies who attended the clinic 12 died, three being breast-fed, nine artificially fed. Of the three breast-fed, one died from an operation for intussusception, one from a congenital blood disease, and one from pneumonia following measles. Of the nine artificially fed four died from ill-feeding, and from respiratory disease following measles or whooping-cough, ill-feeding being a contributory cause of death. Of the 17 children whose life-history was not known five were said to have been breast-fed and 12 artificially fed. Of these breast-fed infants one died from injury, one from syphilis, one from pneumonia, one from bronchitis, and one from pyæmia. Of the artificially-fed "non-clinic" infants, seven apparently died from ill-feeding alone, four from pneumonia following whooping-cough, and one from congenital heart disease. All the clinic children who died were legitimate. Of the others, two were illegitimate and the rest legitimate. The fact that the 90 per cent. of infants who attended the clinics furnished 12 deaths while the 10 per cent. who did not attend furnished 17 deaths indicates that the section of the population for whom attendance at the clinics is most necessary do not use them.

Deaths between 1 and 2 Years of Age.—Fourteen such deaths were registered, 10 being among clinic children. Of the ten clinic children whose history was known five had been breast-fed. Of these, one died from scalds, one from sarcoma of the kidney, and three from pneumonia or bronchitis. Of the five artificially-fed clinic children one died from acute nephritis, one from tuberculous meningitis, three from pneumonia following measles or whooping-cough. Of the four non-clinic children whose history is not properly known, one died from tuberculous meningitis, one from ill-feeding, and two from pneumonia following whooping-cough.

Deaths between the Second and Fifth Year.—Fourteen such deaths occurred, seven among clinic children. Of these latter five were breast and two artificially-fed. Of the breast-fed, one died from scarlet fever, three from pneumonia following measles, and one from tuberculous meningitis. Of the two artificially-fed clinic children one died from appendicitis and one from rickets. Of the seven non-clinic children one died from scalds, one from rheumatic heart disease, one from epilepsy, and four from pneumonia following measles or whooping-cough.

Deaths of Children Aged 5 to 10.—Five such occurred, three being among clinic children. Of the latter, who were all artificially fed in infancy, one died from cerebral tumour, one from rheumatic fever, and one from primary pneumonia. Of the two non-clinic children, one died from epilepsy and one from influenza.

Deaths of Children Aged 10 to 17.—Twelve such children died, but their life-history is not perfectly known. Four died from tuberculosis of the lung, one from tuberculous meningitis, and one from tuberculosis of the spine; one from heart disease, one from pneumonia, one from actinomycosis, one from Bright's disease, one from epilepsy, and one was run over.

It is perfectly obvious from Dr. Brewer's figures that the 10 per cent. of children who do not attend the clinic furnish an undue proportion of deaths up to the age of 10. Dr. Brewer does not think that the severity of the attack furnishes the explanation why one child dies from a disease and another does not, but he thinks the life-history will furnish a sufficient explanation in the case of many diseases such as whooping-cough, pneumonia, and appendicitis. Dr. Brewer goes on to consider the causation of the 26 stillbirths which occurred in Swindon during 1924. No adequate reason is forthcoming for 14. In 12 cases there was some evidence available, but a real explanation only in the case of five which occurred in the maternity home. In the case of one of these five, the fœtus was dead before admission owing to contracted pelvis; in the case of two death was due to asphyxia caused by the impaction of the head in breech presentations; another was due to placenta prævia, and the fifth was a premature puny infant, *theoretically unsaveable. Of the seven other* stillbirths in the case of which some evidence was available, two could be put down to congenital syphilis, one to a toxæmia of pregnancy, one to pneumonia in the mother, and one to an obscure disease of the mother. The two remaining cases were due to complications of delivery, which might have been foreseen and prevented. Of the 26 stillbirths five only had received any kind of antenatal care and all were legitimate. It will be noted that a very large proportion of the 12 stillbirths, about which there was any real evidence as to cause, were theoretically preventable by antenatal work. Swindon has a population of 56,000, about 1000 births annually, and an infant mortality of under 60 for the last three years, but Dr. Brewer's investigations suggest that a more complete scheme (which he outlines in his report) is capable of effecting very great reductions both in the infant mortality-rate and in the death-rates during the year immediately succeeding infancy.

BIRTH NOTIFICATION.

THE early working of the Notification of Births Act of 1907 was intimately bound up with the life of Mr. Benjamin Broadbent, of Huddersfield, whose death was recorded in our columns a fortnight ago. Some interest attaches to the origin of this Act which was the beginning of a general infant welfare campaign. In December, 1904, the medical officer of health for Huddersfield, Dr. S. G. Moore, submitted to his sanitary authority a preliminary report on the measures employed in France and Germany for the protection of infants. In the course of Dr. Moore's inquiries he learned of a small commune in the Midi, Villiers-le-Duc, where for ten years not a single baby had died during its first year of life. To apply similar methods in Huddersfield required a foreknowledge of the existence of the infants to be saved. At that time the books of the Registrar of Births and Deaths afforded the only means of learning this essential fact, and that indirectly after a delay it might be of six weeks. Not infrequently the medical officer saw the names of newly born infants in the death returns of the same date as the birth returns. With the support of the Health Committee, of which Mr. Broadbent was then chairman, Dr. Moore obtained from the sanitary authority sanction for the payment of one shilling to any person who notified to him within 24 hours the birth of an infant. In the following year authority was obtained in a local Act to require the father of a child, if in residence at the house where the birth took place, to make the notification within 36 hours. Failing the father, any person who was in attendance on the mother at the time of birth or within six hours thereafter was required to notify.

A year later Mr. John Burns, President of the Local Government Board, lent powerful support to the Huddersfield clause, and the Notification of Births Act was passed; at first adoptive, in 1915 it was made compulsory. In the work leading up to this conclusion Mr. Broadbent played an active and enthusiastic part, against opposition which was not always good-humoured. An account of the *Huddersfield scheme* is set out in a small brochure which is signed jointly by

B. Broadbent and S. G. Moore. Immediately upon receipt of the notification of birth, upon the same day in all cases, a visit is made by a medical woman, whose responsibility is to ensure that no infant shall perish as the result of ignorance on the part of the mother. After her visit or visits the case is handed over to a voluntary association of ladies who have simply to call from time to time in a friendly way. If they find that the baby is not flourishing they send a post-card to the medical officer of health, whereupon the assistant medical officer revisits and if necessary calls in the family doctor. In no case is medical treatment provided by a member of the staff of the public health department.

There can be little doubt that the movement has preserved thousands of human lives during the last 20 years, as well as greatly reducing crippling, blindness, and ill-health. The Huddersfield records are typical of what the Notification of Births Act has made possible throughout the country. The mean infant mortality figure for that borough prior to 1907, the year when the Huddersfield scheme came into full operation, was 155. For the last few years it has averaged about one-half of that figure, and in some single years it has approached one-third. Coincidently the maternal mortality among those whose pregnancies have been made known to the medical officer of health has fallen from 5–6 per 1000 to 2·5, while the neonatal mortality—deaths under one month—has also been materially reduced. In Huddersfield at the present time there is not a single child of school age blind as the result of ophthalmia neonatorum. There will still remain a doubt in the minds of a section of the medical profession as to the exact part played by "direct measures," such as have been here described, in reducing infant mortality as contrasted with the indirect effects of better general education and the improving of a generation of mothers who had the benefit of the Act of 1870. Bristol has been cited as an example of a city where the decline in the infant mortality-rate was as striking as that of Huddersfield in the absence of direct measures. No doubt the latter were both more necessary and more potent in a town like Huddersfield, where many mothers work in factories. However that may be, Benjamin Broadbent will go down to posterity as a pioneer of the child welfare movement, which marked the first quarter of the twentieth century, and as a friend of humanity at its most helpless age.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXI.

TREATMENT OF EXTERNAL OTITIS AND FURUNCULOSIS OF THE EXTERNAL AUDITORY MEATUS.

INFLAMMATORY implications of the pinna and fibro-cartilaginous external ear are accompanied by symptoms and local manifestations, sometimes almost indistinguishable from those which arise from extensions of primary middle-ear suppurative infection to the cutaneous tissues behind the auricle. Since a mistake may have distressing consequences where the diagnosis is not obvious after careful examination the surgeon should act as if the more serious condition were present, provided always that he feels assured of his skill in the necessary surgical technique; no harm could come from doing a simple mastoidotomy when only the external ear is inflamed, but most severe complications may follow the treatment of mastoid disease on the lines of an external otitis. In practice, however, it is rare for a surgeon in daily contact with these affections to have much difficulty in making the differential diagnosis. The swelling and tenderness has been superficial throughout in external otitis, and has only recently become so in suppurative mastoiditis. In the last-named condition the shape of the external meatus is similar to that of the sound ear, whilst in external otitis it is narrowed, slit-like, red, and very sensitive to touch with the speculum or a probe. In mastoiditis the drum and middle ear show evidence of inflammation, perforation of the membrane, or discharge of pus, whilst in external otitis the drum may be absolutely normal, except in patients who give a history of old middle-ear suppuration. The discharge from the ear in mastoiditis is stringy and sticky, owing to the presence of mucus from the inflamed middle ear, this property being absent from the pus of furuncular origin. Tenderness to touch is localised to movement of the pinna and external meatal tube when they alone are inflamed, and to the tissues over the surface of the mastoid when the bone beneath is involved. Deafness and tinnitus may be common to both conditions, but pain, which is often the dominant symptom, may be even more pronounced in the less grave of the two affections, because the close attachment of the skin to the cartilaginous tube affords little accommodation for inflammatory œdema; moreover, the pressure is rendered still more intense by the unyielding bony walls if the furuncle is deep in the meatus.

Furunculosis is by far the commonest type of external otitis; the differential diagnosis of the other forms met with—diffuse otitis and acute recurring eczema—is much easier.

Diffuse otitis does not tend to point like a furuncle; the inflammatory induration is not definitely circumscribed, but resembles a cellulitis. It may result from a skin abrasion, infection by staphylococci or streptococci, but is occasionally due to the *Bacillus pyocyaneus*, the latter form being much commoner in parts of the continent than in this country.

Acute recurring eczema is not usually included under the heading of otitis externa in text-books, but the acuteness of its onset, the distress it causes, and the frequency with which unresolved patches of eczema in the region of the external meatal orifice act as the starting-point of furuncular and diffuse inflammation, entitles it, in my opinion, to be so included.

Furunculosis.

The treatment of external otitis of furuncular origin must necessarily vary with the stage of the affection. In all cases, to begin with, 3 gr. of calomel should be given at night followed by a saline in the morning. If the patient is seen very early, before inflammatory infiltration is pronounced, touching the point of infection with pure carbolic may cause the furuncle to abort, but care must be taken to prevent the carbolic flowing beyond the exact spot, otherwise an area of skin may be denuded of epithelium and a further infection result. If the exact point cannot be discovered, carbolic oil should be applied with a piece of wool to the entire meatus twice daily. It serves two purposes, the first being to render practically inactive any organism present in the meatus at the time, and the second to act similarly on any fresh organisms entering from without or from pus escaping when the furuncle matures. In mild cases it is ample treatment and prevents the tendency to recurrences. Excessive moisture in the meatus leads to maceration of the epithelium, and as this facilitates reinfection the amount of liquid left behind should be reduced to a minimum, whether it be oil, lotion, or drops. When there is much inflammatory induration present, accompanied by pain, fomentations give considerable relief, and if persisted in for 24 hours will often suffice to bring the furuncle to maturity and spontaneous rupture. It is a moot point whether fomentations favour the occurrence of furuncular crops or not. If too moist they may do so by macerating the epithelium, but probably not otherwise. If carbolic oil has been previously used it should be cleaned off the skin as *carefully as possible or the application of heat over* it may result in a blister. The fomentation by itself will produce a blister if too hot, and is then probably responsible for reinfection and some discredit to an excellent method of treatment. Dry sterile wool in the meatus, concha, and around the pinna, over which a rubber hot water bottle is applied, is very comforting.

Advanced Cases.—When, however, the induration is considerable with some surrounding œdema, the progress of the case is slow, and the pain persists, free incision through the furuncle offers the best prospect of early success. An attempt should be made to render the meatus as sterile as possible by using hydrogen peroxide and syringing with warm boric lotion; under a short general anæsthesia, a short, straight tenotomy knife is then passed into the passage, deep to the furuncle, and carried outwards through its centre and down to the base. It is most important to cut deeply, otherwise the inflammatory tension and pain will persist. Syringe again with the warm lotion, dry out, and dress with a strip of sterile ribbon gauze partially soaked in bipp. The first dressing may remain for 48 hours, but should be changed daily afterwards. In cases where the furuncle has opened spontaneously a daily dressing of gauze or bipp is satisfactory. As lotions are frequently used in treating meatal inflammatory infections it is well to emphasise the risk that maceration of the epithelium may give rise to reinfection. All excessive moisture tends to macerate the skin, but mercurial or carbolic lotions are particularly liable to do so, especially the former.

Recurrences of furunculosis, in my opinion, are often due to the reinfection of denuded areas of skin, resulting either from the inflammatory process or the maceration of epithelium by some fault of the medicament or technique, which with care may be guarded against. However, despite every known precaution, recurrences will take place, when vaccine therapy promises the most effective line of attack. Autogenous vaccines, if obtainable, are the best, but if they are not available stock vaccines are worth a trial. I have seen excellent results from their use in some cases and from such small dosage as 50, 100, and 200 million staphylococci (*pyogenes aureus*) in successive weekly doses.

Diffuse Otitis.

Diffuse otitis is much less common than the furuncular form and is usually an accompaniment of an existing middle-ear suppuration. The treatment follows the same lines as that indicated already in the inflammatory indurations of furunculosis—namely, a sterile drainage-wick in the ear, fomentations, and, if suppuration occurs, surgical incision under general anæsthesia. In the form due to *Bacillus pyocyaneus* a perichondritis is present, but it never suppurates. It may last five or six weeks and tends to recur through reinfection, probably by the patient scratching the meatal orifice with the finger-nail. The organisms usually have their habitat in the axillæ and groins of persons of indifferent hygienic habits and surroundings. Frequent bathing and the application of a weak biniodide of mercury lotion to the groins and axillæ with the daily use of 3 per cent. silver nitrate drops in the ear is the best treatment. As hydrogen peroxide is now so commonly prescribed in the treatment of ear affections, it is interesting to note that if this is used in external otitis of pyocyaneus origin these organisms will flourish luxuriantly.

Acute Recurring Eczema.

Acute recurring eczema responds well to treatment. During the acute stage Lassar's paste (zinc oxide, pulv. amyl, lanolin and vaseline, each 2 dr.) should be applied on strips of muslin or lint (smooth side) over the pinna and in its folds and on a few inches of half-inch ribbon gauze lightly packed into the external meatus, night and morning. Gauze wick will prove useful as a drain from a middle-ear suppression, should such be present, until the condition of the external skin permits of the local use of lotions and drops. When the eczema has passed into the dry and scaly stage, 10 gr. of salicylic acid should be added to the ounce of Lassar's paste and applied direct to the affected area which may be otherwise left uncovered. As eczema of the pinna is invariably accompanied by seborrhœa of the scalp, which in the opinion of some dermatologists is the starting-point of the infective ear process, the scalp should be shampooed about twice a week, taking care to protect the ear from the water or shampoo liquid used. Soap spirit (sapo-mollis and spirit. vini rect. 2 oz. each) acts well, but much care must be taken to remove all traces of it by repeated rinsings of water. In less acute cases of deep meatal eczema (so often the starting-point of external otitis, diffuse and furuncular) the following method gives excellent results. If there is any loose skin débris about, remove it by gentle syringing or wiping out with wool with a solution of sodium bicarbonate, 2 dr. to the pint of warm water. Dry meatus and fill with a rolled pledget of wool soaked in the following preparation.

℞	Ung hydrarg. nitr. dil.	1 dr.
	Liq. carbon. deterg...	10 ♏.
	Paraff. liq.	ad 1 oz.

This oily preparation should be brought into intimate contact with the meatal lining by pressing the tragus on to the wool several times. This wool should be removed and a small dry portion placed in the external orifice only.

JOHN F. O'MALLEY, F.R.C.S. Eng.,
Surgeon, Ear, Nose, and Throat Department,
University College Hospital.

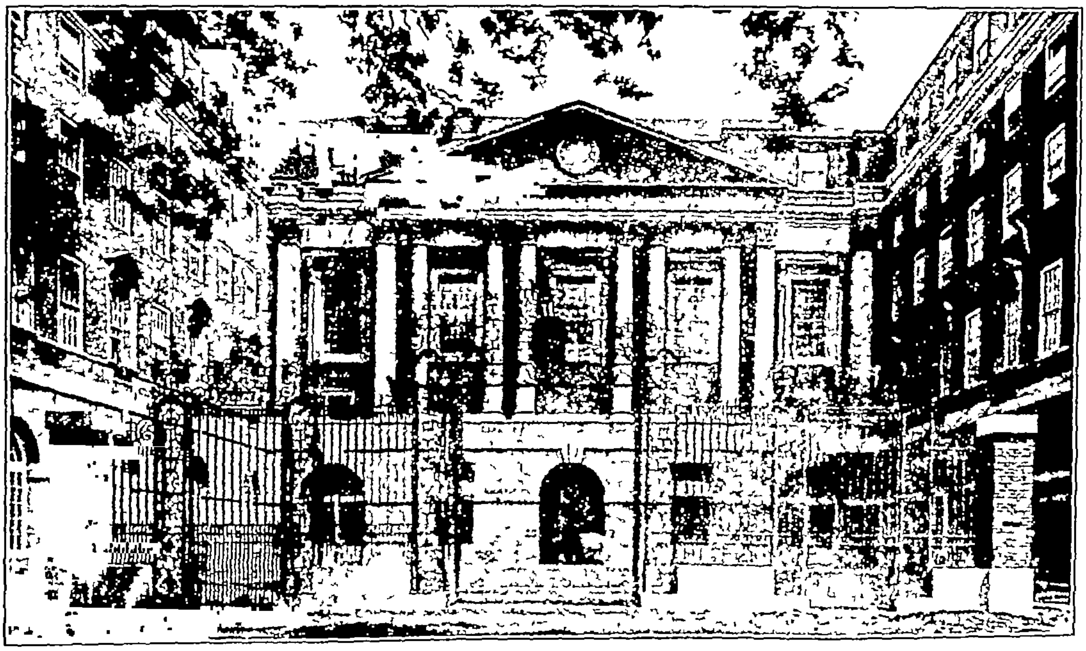
ST. MARYLEBONE HOSPITALS LEAGUE.—Mr. Walter Kewley, house governor of the Middlesex Hospital, calls attention to the work of the St. Marylebone Hospitals League, founded in 1923, and urges its imitation elsewhere. The fundamental principles of the League are the recognition of the obligation upon all people to support the hospitals and "appreciation of the fact that medical education, research work, and the training of nurses are primarily their most important functions"—that is to say, if there were no poor the hospitals would still be essential. To the preaching of this doctrine he ascribes the success of the League.

Special Articles.

THE OPENING OF THE NEW BRITISH MEDICAL ASSOCIATION HOUSE.

On Monday last, July 13th, His Majesty the King opened the new home of the British Medical Association at Tavistock-square, London.

A full hour before the ceremony nearly all the delegates had taken their places in the Great Hall, and the square between the new memorial gates and the magnificent buildings was thronged with the representatives of the medical colleges and the nursing associations, along with visitors whose connexion with medicine entitled them to the honour of welcoming the King with his medical hosts. The band of the Grenadier Guards was already playing on the circular lawn, and alternated with a hidden string orchestra, also from the Grenadiers, whose music was relayed to the courtyard and the Great Hall by electrical amplifiers. Many visitors occupied a covered stand just outside the gates on the south side. At a quarter to three a guard of honour marched up—the Artists' Rifles—headed by a fife band in silver-grey, and took post along the short approach from Tavistock-square, which was brilliantly decorated with ornamental columns wound with flowers. At five minutes to three His Grace the Archbishop of Canterbury, escorted by the President, Mr. J. Basil Hall, the architect, Sir Edwin Lutyens, and seven of the leaders of the profession in Great Britain, offered prayer and solemnly dedicated the gates to the memory of the 574 members of the Association who gave their lives in the war. His Grace then took the key from the architect and opened the gates. The Guards played the hymn, "O God, our Help" before the dedication and "Abide with Me" as the gates swung open. The ceremony was impressive in its sincerity and restraint.



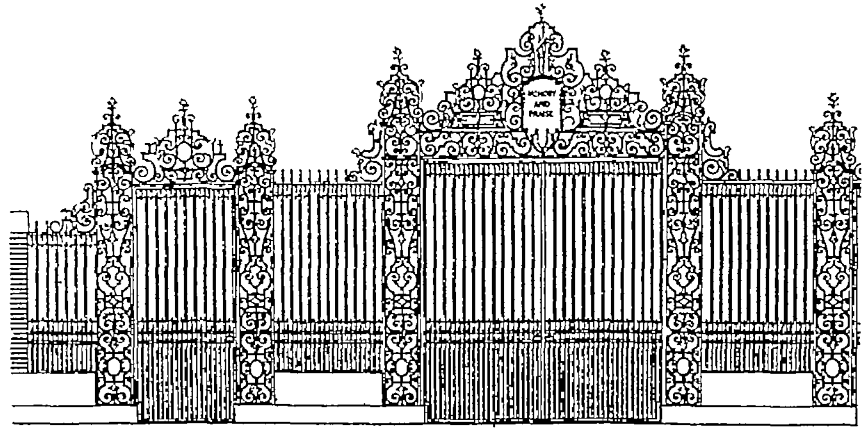
Courtyard of the British Medical Association House. [*Topical Press Photo.*

At ten minutes past three the King and Queen arrived with their attendants, accompanied by Mr. Neville Chamberlain, the Minister of Health. The Royal Standard broke from the flagstaff above the central pediment, and the Artists' band played the National Anthem. His Majesty then inspected the guard of honour, commanded by Captain W. Campbell Smith, M.C. The Minister of Health then presented the President of the Association, Mr. J. Basil Hall, of Bradford, and the Chairman of Council, Dr. R. A. Bolam, of Newcastle-on-Tyne; and the Chairman of the Council presented Dr. H. B. Brackenbury (Chairman of the Representative Body of the Association); Mr. N. Bishop Harman (Treasurer of the Association); Sir Donald MacAlister, Bart. (President of the General Medical Council); Sir Humphry Rolleston, Bart. (President of the Royal College of Physicians); Sir John Bland-Sutton, Bart. (President of the Royal College of Surgeons); Lord Dawson of Penn; Sir George Newman (Chief Medical Officer to the Ministry of Health); Sir Edwin Lutyens (the architect of the building); and Mr. F. J. Walton (the contractor). Those who had been presented then formed a procession and escorted the King and Queen through the courtyard and the main entrance to the Members' Reception Room. There the Royal visitors met the Reception Committee, and the Chairman of the Council presented Sir Dawson Williams, the Editor of the *British Medical Journal*, and other distinguished medical men and women, as well as the representatives of the workmen who had made the building, and the organising staff who had directed their work.

Meanwhile the Great Hall, with its cheerful white walls and friezes and its peacock-blue columns, held a crowded audience of delegates, who filled floor and gallery, their scarlet gowns and coloured hoods making a brilliant show. The procession mounted the dais to the enthusiastic singing of the National Anthem, and the Chairman of the Council welcomed His Majesty in an address in which he traced the history of the B.M.A. since it was founded by Sir Charles Hastings in 1832, set out its aims and scope, and mentioned its debt of gratitude to the King, who had succeeded his father King Edward as Patron.

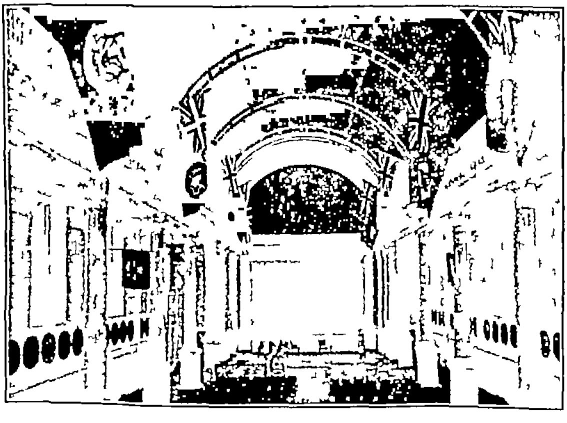
His Majesty replied most sympathetically. He said he felt great pride at succeeding his Royal father as the patron of such a noble society, and paid tribute to the splendid work of the B.M.A. in selecting and training recruits to the professon, in criticising and

assisting research, in uniting the medical activities of the country, and in maintaining the very high standards that now governed the practice of medicine. Noble traditions were a priceless possession that must be not only maintained but constantly increased



The Memorial Gates

He admired especially the promotion of post-graduate study He warned the profession of their deep responsibility for the general health of the country, and indicated the value of administration in maintaining sanitation in factories and public buildings and places and in preventing epidemic disease, and also of the informal education that the general practitioner can give the lay public in personal health and general hygiene.



The Great Hall.

He thanked the Association on behalf of the Queen for the reference to her interest in the practice of medicine by women, who were now active in all its branches. He expressed especial pleasure at the harmony he observed to exist between the Medical Association in this country and those in the Great Dominions of the Empire, and was honoured to welcome the representatives of America, France, Holland Sweden, Norway, and Denmark

Sir Edwin Lutyens then presented a master key to His Majesty, who declared the building open, and congratulated the members on their new and dignified home.

The Chairman of the Council then presented the representatives of the Home, Imperial, and Foreign Associations. The King and Queen then left the Great Hall and inspected the library, where the King accepted a copy of an illuminated Roll of Honour, the work of Mr F G Hallett. After a tour of the building and grounds Their Majesties returned to the gates and took leave of the President and representatives of the Committee Mr Bishop Harman, the Treasurer, led the cheers as the Royal carriages drove off

After the ceremony the building was open to inspection by the guests. As at present completed it covers an area of 18,000 square feet and has a total floor area of 58,000 square feet. It is built in an austere style of red brick with white stone facings, and is approached from Tavistock-square by a short roadway, which will, in due course, be bordered by wings extending out from the Association building Beneath the Great Hall runs a vestibule connecting the Court of Honour with the entrance in Burton-street, so that cars are able to drive straight through after depositing their passengers. For the owner-driver there is ample covered parking room behind the building In the centre of the Court of Honour is a circular grass plot curbed with white stone, while the corners are paved with flagstones. The gates are of wrought iron in an eighteenth-century design prepared by Sir Edward Lutyens, painted black, and surmounted by a bronze shield lettered in gold The

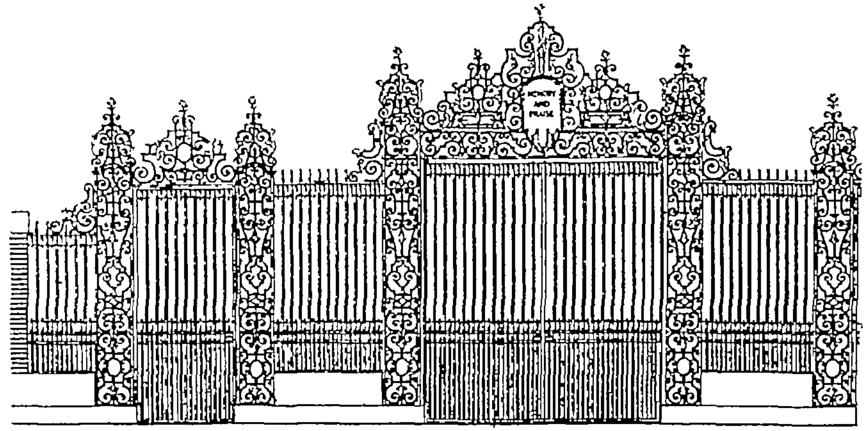
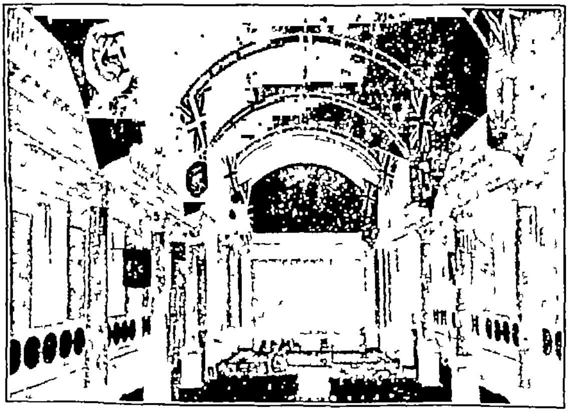
assisting research, in uniting the medical activities of the country, and in maintaining the very high standards that now governed the practice of medicine. Noble traditions were a priceless possession that must be not only maintained but constantly increased.



The Memorial Gates

He admired especially the promotion of post-graduate study. He warned the profession of their deep responsibility for the general health of the country, and indicated the value of administration in maintaining sanitation in factories and public buildings and places and in preventing epidemic disease, and also of the informal education that the general practitioner can give the lay public in personal health and general hygiene.

He thanked the Association on behalf of the Queen for the reference to her interest in the practice of medicine by women, who were now active in all its branches. He expressed especial pleasure at the harmony he observed to exist between the Medical Association in this country and those in the Great Dominions of the Empire, and was honoured to welcome the representatives of America, France, Holland, Sweden, Norway, and Denmark.



The Great Hall

Sir Edwin Lutyens then presented a master key to His Majesty, who declared the building open, and congratulated the members on their new and dignified home.

The Chairman of the Council then presented the representatives of the Home, Imperial, and Foreign Associations. The King and Queen then left the Great Hall and inspected the library, where the King accepted a copy of an illuminated Roll of Honour, the work of Mr. F. G. Hallett. After a tour of the building and grounds Their Majesties returned to the gates and took leave of the President and representatives of the Committee. Mr. Bishop Harman, the Treasurer, led the cheers as the Royal carriages drove off.

After the ceremony the building was open to inspection by the guests. As at present completed it covers an area of 18,000 square feet and has a total floor area of 58,000 square feet. It is built in an austere style of red brick with white stone facings, and is approached from Tavistock-square by a short roadway, which will, in due course, be bordered by wings extending out from the Association building. Beneath the Great Hall runs a vestibule connecting the Court of Honour with the entrance in Burton-street, so that cars are able to drive straight through after depositing their passengers. For the owner-driver there is ample covered parking room behind the building. In the centre of the Court of Honour is a circular grass plot curbed with white stone, while the corners are paved with flagstones. The gates are of wrought iron in an eighteenth-century design prepared by Sir Edward Lutyens, painted black, and surmounted by a bronze shield lettered in gold. The

Special Articles.

THE OPENING OF THE NEW BRITISH MEDICAL ASSOCIATION HOUSE.

On Monday last, July 13th, His Majesty the King opened the new home of the British Medical Association at Tavistock-square, London.

A full hour before the ceremony nearly all the delegates had taken their places in the Great Hall, and the square between the new memorial gates and the magnificent buildings was thronged with the representatives of the medical colleges and the nursing associations, along with visitors whose connexion with medicine entitled them to the honour of welcoming the King with his medical hosts. The band of the Grenadier Guards was already playing on the circular lawn, and alternated with a hidden string orchestra, also from the Grenadiers, whose music was relayed to the courtyard and the Great Hall by electrical amplifiers. Many visitors occupied a covered stand just outside the gates on the south side. At a quarter to three a guard of honour marched up—the Artists' Rifles—headed by a fife band in silver-grey, and took post along the short approach from Tavistock-square, which was brilliantly decorated with ornamental columns wound with flowers. At five minutes to three His Grace the Archbishop of Canterbury, escorted by the President, Mr. J. Basil Hall, the architect, Sir Edwin Lutyens, and seven of the leaders of the profession in Great Britain, offered prayer and solemnly dedicated the gates to the memory of the 574 members of the Association who gave their lives in the war. His Grace then took the key from the architect and opened the gates. The Guards played the hymn, "O God, our Help" before the dedication and "Abide with Me" as the gates swung open. The ceremony was impressive in its sincerity and restraint.

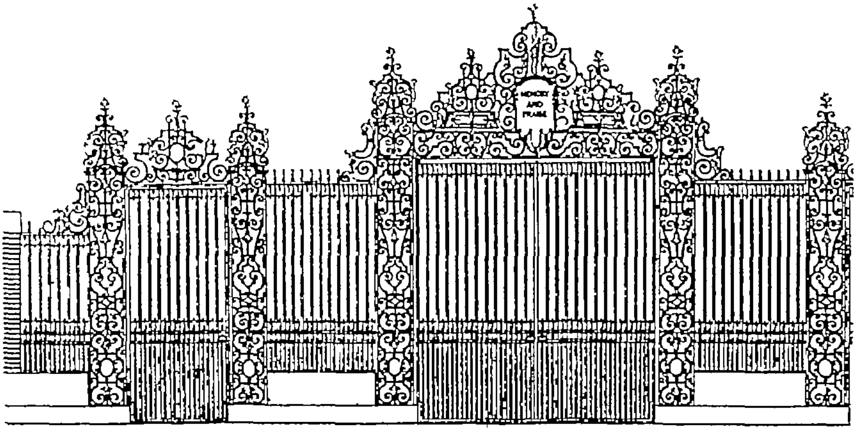
Courtyard of the British Medical Association House. [*Topical Press Photo.*

At ten minutes past three the King and Queen arrived with their attendants, accompanied by Mr. Neville Chamberlain, the Minister of Health. The Royal Standard broke from the flagstaff above the central pediment, and the Artists' band played the National Anthem. His Majesty then inspected the guard of honour, commanded by Captain W. Campbell Smith, M.C. The Minister of Health then presented the President of the Association, Mr. J. Basil Hall, of Bradford, and the Chairman of Council, Dr. R. A. Bolam, of Newcastle-on-Tyne; and the Chairman of the Council presented Dr. H. B. Brackenbury (Chairman of the Representative Body of the Association); Mr. N. Bishop Harman (Treasurer of the Association); Sir Donald MacAlister, Bart. (President of the General Medical Council); Sir Humphry Rolleston, Bart. (President of the Royal College of Physicians); Sir John Bland-Sutton, Bart. (President of the Royal College of Surgeons); Lord Dawson of Penn; Sir George Newman (Chief Medical Officer to the Ministry of Health); Sir Edwin Lutyens (the architect of the building); and Mr. F. J. Walton (the contractor). Those who had been presented then formed a procession and escorted the King and Queen through the courtyard and the main entrance to the Members' Reception Room. There the Royal visitors met the Reception Committee, and the Chairman of the Council presented Sir Dawson Williams, the Editor of the *British Medical Journal*, and other distinguished medical men and women, as well as the representatives of the workmen who had made the building, and the organising staff who had directed their work.

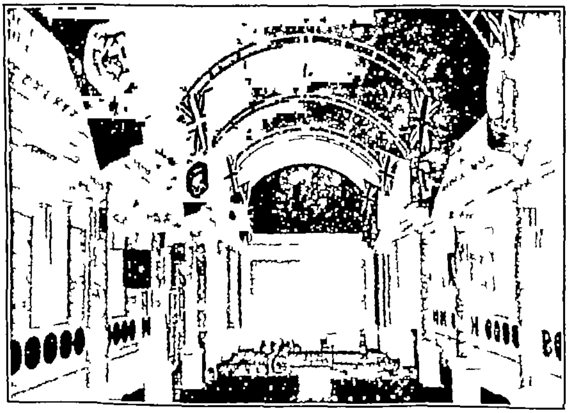
Meanwhile the Great Hall, with its cheerful white walls and friezes and its peacock-blue columns, held a crowded audience of delegates, who filled floor and gallery, their scarlet gowns and coloured hoods making a brilliant show. The procession mounted the dais to the enthusiastic singing of the National Anthem, and the Chairman of the Council welcomed His Majesty in an address in which he traced the history of the B.M.A. since it was founded by Sir Charles Hastings in 1832, set out its aims and scope, and mentioned its debt of gratitude to the King, who had succeeded his father King Edward as Patron.

His Majesty replied most sympathetically. He said he felt great pride at succeeding his Royal father as the patron of such a noble society, and paid tribute to the splendid work of the B.M.A. in selecting and training recruits to the professon, in criticising and

assisting research, in uniting the medical activities of the country, and in maintaining the very high standards that now governed the practice of medicine. Noble traditions were a priceless possession that must be not only maintained but constantly increased He admired especially the promotion of post-graduate study He warned the profession of their deep responsibility for the general health of the country, and indicated the value of administration in maintaining sanitation in factories and public buildings and places and in preventing epidemic disease, and also of the informal education that the general practitioner can give the lay public in personal health and general hygiene.



The Memorial Gates



The Great Hall.

He thanked the Association on behalf of the Queen for the reference to her interest in the practice of medicine by women, who were now active in all its branches. He expressed especial pleasure at the harmony he observed to exist between the Medical Association in this country and those in the Great Dominions of the Empire, and was honoured to welcome the representatives of America, France, Holland Sweden Norway, and Denmark

Sir Edwin Lutyens then presented a master key to His Majesty, who declared the building open, and congratulated the members on their new and dignified home.

The Chairman of the Council then presented the representatives of the Home, Imperial, and Foreign Associations. The King and Queen then left the Great Hall and inspected the library, where the King accepted a copy of an illuminated Roll of Honour, the work of Mr F G Hallett. After a tour of the building and grounds Their Majesties returned to the gates and took leave of the President and representatives of the Committee Mr Bishop Harman, the Treasurer, led the cheers as the Royal carriages drove off

After the ceremony the building was open to inspection by the guests. As at present completed it covers an area of 18 000 square feet and has a total floor area of 58,000 square feet It is built in an austere style of red brick with white stone facings, and is approached from Tavistock-square by a short roadway, which will, in due course, be bordered by wings extending out from the Association building Beneath the Great Hall runs a vestibule connecting the Court of Honour with the entrance in Burton-street so that cars are able to drive straight through after depositing their passengers. For the owner-driver there is ample covered parking room behind the building In the centre of the Court of Honour is a circular grass plot curbed with white stone, while the corners are paved with flagstones. The gates are of wrought iron in an eighteenth-century design prepared by Sir Edward Lutyens, painted black, and surmounted by a bronze shield lettered in gold The inscriptions on either side of the shield are "Memory and Praise" and "Faithful hath been your warfare."

On either side of the passage-way lie beneath the Great Hall the members' lounge and library, the latter panelled with the rare Spanish mahogany familiar to members in the library at the old building. The former is finished in white and a delicate grey, with narrow black skirting. Beneath these rooms are large basements containing staff dining-rooms and storage offices. In the basement of the north wing is the Hastings Hall, capable of seating 150 persons, decorated in white and pale yellow and lighted by inverted bowls resting on gilt pedestals. Similar in design is the Council room in the basement of the south wing, fitted with tiered seats of green morocco, and lined with oak panelling bearing the names of past holders of the high offices of the Association. On the higher floors are committee rooms, office accommodation for the editorial, finance, and intelligence departments, and the printing offices.

If this ceremony is an omen of the future of the Association, no one need fear for British medicine. In its dignified brevity and order it splendidly expressed the unity and purpose of the B.M.A. They have set themselves a high standard, but no one can doubt that they will fulfil it.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING AT BATH.

PROGRAMME OF THE SCIENTIFIC SECTIONS.

THESE sections will meet from 10 A.M. to 1 P.M. on Wednesday, Thursday, and Friday, July 22nd, 23rd, and 24th, for papers and discussions, and it is hoped that laboratory and clinical demonstrations will be arranged for the afternoons. The following sections will meet on each of the three days:—

Medicine.

President: Lord Dawson. Vice-Presidents: Dr. E. J. Cave, Dr. T. R. Elliott, Prof. J. A. Nixon, Prof. Adam Patrick, Dr. W. N. West Watson. Hon. Secretaries: Dr. James Lindsay, 1, The Circus, Bath; Dr. F. G. Chandler, 1, Park-square West, Portland-place, London, N.W. 1.

Provisional Programme.—July 22nd.—Discussion: Rheumatoid Arthritis, its Causation and Treatment. To be opened by Sir Humphry Rolleston, followed by Dr. Rupert Waterhouse (Treatment), Sir Robert Jones (Surgical), Dr. J. M. H. Monro (Bacteriology), Mr. A. G. Timbrell Fisher (Pathological), Mr. W. R. Ackland (Dental), and Sir William H. Willcox.

July 23rd.—Discussion: Hyperpiesis. To be opened by Lord Dawson; followed by Prof. E. H. Starling, Dr. H. Batty Shaw, Dr. Otto May, and Dr. Geoffrey Evans.

July 24th.—Discussion: The Uses and Abuses of Endocrine Therapy. To be opened by Dr. W. Langdon Brown and Prof. Swale Vincent; followed by Dr. H. Gardiner-Hill, Mr. Kenneth M. Walker, Dr. H. W. C. Vines, and Prof. F. S. Langmead.

Surgery.

President: Sir Berkeley Moynihan. Vice-Presidents: Mr. A. H. Burgess, Mr. Frederick Lace, Mr. H. S. Souttar, Mr. C. F. Walters. Hon. Secretaries: Mr. A. de V. Blathwayt, 6, Brock-street, Bath; Mr. A. L. Fuller, 9, Gay-street, Bath; Mr. R. M. Vick, 152, Harley-street, London, W. 1.

Provisional Programme.—July 22nd.—Discussion: Carcinoma of the Stomach. To be opened by Sir W. I. de Courcy Wheeler; followed by Dr. E. I. Spriggs (Clinical Manifestations and Early Diagnosis), Dr. A. F. Hurst (Auxiliary Methods of Diagnosis, Radiological and Chemical), Prof. M. J. Stewart (Pathology: General Relation of Carcinoma to Ulcer; Mode of Spread and Frequency of Secondary Deposits in Liver), Mr. J. Sherren, Mr. John Morley, Dr. J. A. Nixon, and Mr. A. H. Burgess.

July 23rd.—Discussion: Acute Intestinal Obstruction. To be opened by Sir William Taylor; followed by Mr. W. Sampson Handley and Mr. D. P. D. Wilkie. A general report and statistics from various hospitals for the past five years will be presented by Mr. H. S. Souttar (London Hosp.), Mr. R. P. Rowlands (Guy's), Mr. C. Max Page (St. Thomas's), Mr. R. M. Vick (St. Bartholomew's), Mr. L. R. Braithwaite (Leeds), Mr. G. Grey Turner (Newcastle), Mr. A. H. Burgess (Manchester), Mr. A. Rendle Short (Bristol), and Mr. A. B. Mitchell (Belfast).

July 24th.—Combined discussion with Orthopædic Section: Treatment of Fractures, with special reference to its Organisation and Teaching. To be opened on the Surgical side by Mr. G. E. Gask; followed by Mr. S. W. Daw, Mr. H. Wade, Mr. H. H. Sampson, and Mr. A. W. Sheen; and on the Orthopædic side by Sir Robert Jones; followed by Dr. R. Osgood (Boston, U.S.A.), Mr. H. Platt, Mr. H. A. T. Fairbank, Mr. C. Max Page, and Mr. Gwynne E. O. Williams.

Obstetrics and Gynæcology.

President: Lady Barrett. Vice-Presidents: Mr. H. S. Davidson, Mr. Eardley L. Holland, Mr. W. F. Rawson, Mr. D. C. Rayner. Hon. Secretaries: Mr. W. H. Duncan, 13, Gay-street, Bath; Dr. J. Bright Banister, 19, Harley-street, London, W. 1.

Provisional Programme.—July 22nd.—Discussions: (*a*) The Problems of Uterine Cancer. To be opened by Prof. B. P. Watson. (*b*) The Surgical Treatment of Malignant Disease of the Pelvic Organs. To be opened by Mr. Victor Bonney and Mr. S. J. Cameron. The following will take part in the discussions: Prof. C. Oldfield, Mr. H. J. D. Smythe, Dr. R. S. S. Statham, and Prof. W. C. Swayne.

July 23rd.—Discussion: The Treatment of Inoperable Cancer of the Pelvic Organs. To be opened by Dr. James Heyman (Stockholm); followed by Mr. Percival P. Cole and Mr. Malcolm Donaldson. Paper: Dr. D. C. Hare: Preliminary Investigation into the Circulatory Changes in Normal Pregnancies.

July 24th.—Discussion: The Rôle of Surgery in the Treatment of Backward Displacement of the Uterus. To be opened by Miss M. H. Frances Ivens; followed by Dr. H. Russell Andrews, Prof. J. M. Munro Kerr, Mr. R. H. Paramore, Mr. D. C. Rayner, Mr. D. Shannon, and Sir Henry J. F. Simson.

Pathology and Bacteriology.

President: Prof. J. C. G. Ledingham. Vice-Presidents: Dr. J. A. Braxton Hicks, Prof. E. H. Kettle, Dr. Rupert Waterhouse. Hon. Secretaries: Lieut.-Colonel James Cowan, 44, Combe-park, Bath; Dr. C. C. Okell, Wellcome Physiological Research Laboratories, Langley Court, Beckenham, Kent.

Provisional Programme.—July 22nd.—Discussion: Filter-passing Viruses. To be opened by Dr. W. E. Gye; followed by Mr. J. E. Barnard, Dr. Mervyn H. Gordon, Dr. S. P. Bedson, and Dr. J. E. McCartney.

July 23rd.—Discussion: The Pathological Basis of Treatment by Radiation. To be opened by Prof. S. Russ; followed by Dr. T. S. P. Strangeways, Miss M. E. Hume, and Dr. A. Piney.

July 24th.—Discussion: The Present Position of Pathology and Bacteriology in this Country, with special reference to Research. To be opened by the President of the section.

Neurology and Psychological Medicine.

President: Sir Maurice Craig. Vice-Presidents: Prof. Edwin Bramwell, Dr. Arthur F. Hurst, Dr. Norman Lavers, Dr. S. A. K. Wilson. Hon. Secretaries: Dr. Ray Edridge, 29, Gay-street, Bath; Dr. Edward Mapother, Maudsley Hospital, Denmark Hill, London, S.E. 5.

Provisional Programme.—July 22nd.—Discussion: Causation and Symptomatology of Multiple Neuritis. To be opened by Dr. T. Grainger Stewart; followed by Dr. James S. Collier, Dr. Wilfred J. Harris, Dr. W. Johnson, and Dr. F. J. Nattrass.

July 23rd.—Discussion: Treatment of Insomnia. To be opened by Dr. Robert Hutchison; followed by Dr. Harry Campbell, Dr. Henry Devine, and Dr. C. P. Symonds.

July 24th.—Discussion: Prophylaxis of Mental Disorder. To be opened by Sir Humphry Rolleston; followed by Dr. A. Helen A. Boyle, Dr. Bernard Hart, Dr. Edward Mapother, and Dr. T. A. Ross.

Therapeutics (including Balneology and Radiotherapy).

President: Prof. R. B. Wild. Vice-Presidents: Dr. Preston King, Dr. W. Mitchell, Dr. Nathan Mutch. Hon. Secretaries: Dr. Cecil H. Terry, 15, The Circus, Bath; Dr. Dorothy C. Hare, 1, Bickenhall Mansions, London, W. 1.

Provisional Programme.—July 22nd.—Discussion: Treatment of Asthma. To be opened by Dr. W. Langdon Brown, followed by Dr. E. P. Poulton, and Dr. P. Hamill.

July 23rd.—Discussion: Treatment of Chronic Arthritis. To be opened by Sir Thomas Horder; followed by Dr. C. B. Heald, Dr. Preston King (Balneology), Dr. N. Mutch, and Dr. C. B. Heald.

July 24th.—Discussion: Therapeutic Value of Light. To be opened by Prof. W. E. Dixon; followed by Dr. C. E. M. Jones (Clinical) and Dr. G. H. Lancashire. Paper: Dr. Newman Neild: The Uses of Posture for Bronchial Drainage.

Laryngology, Otology, and Rhinology.

President: Mr. Arthur H. Cheatle. Vice-Presidents: Mr. Neil Maclay, Dr. Irwin Moore, Mr. Sydney R. Scott. Hon. *Secretaries: Mr. H. N. Barnett, 27, The Circus, Bath;* Dr. R. Scott Stevenson, 30, New Cavendish-street, London, W. 1.

Programme.—July 22nd.—Discussion: Overlooked Cases of Foreign Body in the Air and Food Passages. To be opened by Prof. Chevalier Jackson (Philadelphia); followed by Dr. Thomas McCrae (Philadelphia), Sir StClair Thomson, and others. Prof. Chevalier Jackson: (a) Demonstration on the Extraction of Foreign Bodies from the Air and Food Passages; (b) Cinematographic demonstration of Bronchoscopic Aspiration for Suppurative Diseases of the Lung of *other than Foreign Body Origin. Dr. T. McCrae:* Bronchoscopy for Disease. Mr. V. E. Negus: Evolutionary Factors in Causation of Pharyngeal Diverticula. Dr. Irwin Moore: An Outline of the History of Endoscopy.

July 23rd.—Discussions: (1) Operative Treatment of Chronic Middle-ear Suppuration. To be opened by Mr. G. J. Jenkins; followed by Mr. Sydney R. Scott, Mr. J. S. Fraser, and Mr. J. Bowring Horgan. (2) Treatment of Chronic Non-suppurative Middle-ear Deafness (excluding *Oto-sclerosis*). To be opened by Sir William Milligan; followed by Dr. J. Kerr Love, Sir Robert Woods, Mr. Neil Maclay, and Mr. H. Norman Barnett.

July 24th.—Discussion: Occupational Diseases of Ear, Nose, and Throat, and their Prevention. To be opened by Mr. F. H. Westmacott; followed by Surgeon-Commander S. W. Grimwade, Wing-Commander D. Rankon, Mr. T. Jefferson Faulder, Mr. C. A. Scott Ridout, and Mr. T. Ritchie Rodger.

The following Sections will each meet on two days:—

Diseases of Children.

President: Dr. Robert Hutchison. Vice-Presidents: Dr. Carey F. Coombs, Mr. P. T. Crymble, Dr. Charles McNeil, Dr. Reginald H. Miller. *Hon. Secretaries: Dr.* Vincent Coates, M.C., 10, The Circus, Bath; Mr. R. A. Ramsay, 123, Gloucester-terrace, Hyde Park, London, W. 2.

Provisional Programme.—July 22nd.—Joint discussion with the Section of Public Medicine: Rheumatic Infection in Childhood—*Early Diagnosis and Preventive* Treatment. To be opened by Dr. F. J. Poynton and Dr. R. A. Askins (M.O.H. Bristol); followed by Dr. Carey F. Coombs, Dr. Reginald Miller, Dr. J. A. Glover (Ministry of Health), and Dr. *Vincent Coates.*

July 23rd.—Discussion: Treatment of Empyema. To be opened by Dr. H. C. Cameron and Mr. H. S. *Souttar*; followed by Dr. F. G. Chandler, Mr. H. W. C. Romanis, and Mr. T. Twistington Higgins.

Ophthalmology.

President: Dr. W. Marlon Beaumont. Vice-Presidents: Dr. R. Wallace Henry, Mr. A. W. Ormond, Mr. C. H. Walker. *Hon. Secretaries:* Dr. R. *Colley*, 30, The Circus, Bath; Mr. P. G. Doyne, 8, Harley-street, London, W. 1.

Provisional Programme.—July 22nd.—Discussion: Eye Injuries and Interstitial Keratitis. To be opened by Mr. W. T. Holmes Spicer.

Papers: Mr. A. W. Ormond, Visual Hallucinations of Sane People. Mr. N. Bishop Harman: Phlyctenular Conjunctivitis and Keratitis—Causes and Prevention. Dr. R. Wallace Henry: Instrument for Recording Light Minimum and Light Difference. *Dr. R. Colley: Case of* Perforating Wound of Eye with Retention of Piece of Glass.

July 23rd.—Discussion: Ocular Pain. To be opened by Mr. A. Freeland Fergus.

Papers: Mr. C. H. Walker: Amaurosis. Mr. Lindsay Rea: Treatment of Ocular Syphilis. Mr. J. Burdon-Cooper: Conservative Treatment of Glaucoma.

Orthopædics.

President: *Prof. E. W. Hey Groves.* Vice-Presidents: Dr. Naughton Dunn, Mr. G. R. Girdlestone, Mr. E. Muirhead Little. Hon. Secretaries: Dr. J. S. *Levis, M.C., 20, Gay-*street, Bath; Mr. T. Twistington *Higgins*, 37, Harley-street, London, W. 1.

Provisional Programme.—July 23rd.—Discussion: Tuberculous Disease of the Spine. To be opened by Prof. Calvé (Paris); *followed* by Mr. G. R. Girdlestone, Mr. W. T. G. Pugh, and Mr. James Russell.

July 24th.—Joint discussion with Section of Surgery on the Treatment of Fractures, with special reference to Organisation and Teaching. (See above.)

Public Medicine.

President: Dr. T. Eustace Hill. Vice-Presidents: Dr. T. W. Naylor Barlow, Dr. J. F. Blackett, Dr. W. A. Brend, Dr. S. Noy Scott. *Hon. Secretaries:* Dr. R. E. Thomas, 11, Darlington-place, Bath; Dr. A. Neville Cox, 21, Cornwall-gardens, *Preston Park*, Brighton.

Provisional Programme.—July 22nd.—Joint discussion *with the Section of Diseases of Children: Rheumatic Infection* in Childhood—Early Diagnosis and Preventive Treatment. *To be opened by Dr. F. J. Poynton* (Children's Section) and Dr. R. A. Askins, School Medical Officer and M.O.H. Bristol (Public Medicine Section).

July 23rd.—Discussions: (1) Food Manipulation in Relation to Health. To be opened by Dr. W. G. Savage. *Dr. C. E. Goddard will speak with special reference to* Accidental Contamination. (2) Influence of Sunlight and Artificial Lights on Health, including Smoke Pollution. To be opened by Dr. Leonard Hill; followed by Dr. G. B. *Dixon, who will speak particularly on the Influence of* Light on Tuberculosis, and Dr. Dora C. Colebrook.

The following Section will meet on one day:—

Medical Sociology.

President: Dr. Charles E. S. Flemming. Vice-Presidents: Dr. J. W. Bone, Mr. Wilfred Buckley, Mr. G. P. Male, Dr. E. A. Starling. Hon. Secretaries: Dr. C. A. Marsh, The Roseries, Englishcombe, Bath; Dr. C. J. Buchan, 326, Brownhill-road, Catford, London, S.E. 6.

Provisional Programme.—July 24th.—Morning.—Discussion: What should be the Standard of Purity of Milk? To be opened by Dr. R. Stenhouse Williams, from the point of view of the bacteriologist; Dr. W. G. Savage, from the *point of view of the medical officer of health; and Dr. Eric* Pritchard, from the point of view of the dietist. Afternoon.—*Discussion: By What Means can Pure Milk be Obtained,* and the Cost? To be opened by Mr. Wilfred Buckley (National Clean Milk Society), *as a producer; Mr. G. P.* Male, as a veterinary surgeon; and Mr. J. H. Maggs (chairman, United Dairies), as a distributor. Two films will be *shown with the following titles: Production of Certified* Milk on an English Farm, and Handling and Distribution of Milk in New York City.

THE BRITISH SOCIAL HYGIENE COUNCIL

(LATE NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES).

THE British Social Hygiene Council held their *tenth annual meeting* on July 6th in the Robert Barnes Hall of the Royal Society of Medicine. *Sir* Auckland Geddes delivered the presidential address.

Annual Meeting.

The President, in his opening *remarks*, paid a tribute to his predecessor, Lord Trevethin, who had done so much to combat venereal disease. He went on to point out the unusual interest of the occasion; the Council was now looking back over 11 years of activity and difficulty during which great progress had been made. Between the years 1920 and 1924 the *numbers of new cases of syphilis* at the treatment centres had fallen from 48,000 *to 22,000*, while the number of attendances had risen from under 1,500,000 to 1,645,000. It was clear from *these figures and* others that venereal disease had been combated in this country with increasing *success, though the end was not yet in sight.* The British Social Hygiene Council, coöperating with the Ministry *of* Health and the local authorities, had done a great deal towards this result. In order to *determine* the *aims* of the Council for the future it was necessary to consider what the reduction of venereal disease would mean not only for the present generation but for posterity. The figures quoted showed that the number of new infections had definitely diminished, so that every unborn child had a proportionately greater chance of escaping infection. The Council looked forward over a vast field of effort, and while they saw clearly that medical work against venereal disease was profoundly important and was progressing rapidly, yet the problem had many other aspects. There was no group of diseases in which medical, social, and moral problems were so inextricably interwoven, and medicine could not achieve victory over venereal disease by itself. The change in their inscriptions on either side of the shield are "Memory and Praise" and "Faithful hath been your warfare."

On either side of the passage-way lie beneath the Great Hall the members' lounge and library, the latter panelled with the rare Spanish mahogany familiar to members in the library at the old building. The former is finished in white and a delicate grey, with narrow black skirting. Beneath these rooms are large basements containing staff dining-rooms and storage offices. In the basement of the north wing is the Hastings Hall, capable of seating 150 persons, decorated in white and pale yellow and lighted by inverted bowls resting on gilt pedestals. Similar in design is the Council room in the basement of the south wing, fitted with tiered seats of green morocco, and lined with oak panelling bearing the names of past holders of the high offices of the Association. On the higher floors are committee rooms, office accommodation for the editorial, finance, and intelligence departments, and the printing offices.

If this ceremony is an omen of the future of the Association, no one need fear for British medicine. In its dignified brevity and order it splendidly expressed the unity and purpose of the B.M.A. They have set themselves a high standard, but no one can doubt that they will fulfil it.

BRITISH MEDICAL ASSOCIATION:
ANNUAL MEETING AT BATH.

PROGRAMME OF THE SCIENTIFIC SECTIONS.

THESE sections will meet from 10 A.M. to 1 P.M. on Wednesday, Thursday, and Friday, July 22nd, 23rd, and 24th, for papers and discussions, and it is hoped that laboratory and clinical demonstrations will be arranged for the afternoons. The following sections will meet on each of the three days:—

Medicine.

President: Lord Dawson. Vice-Presidents: Dr. E. J. Cave, Dr. T. R. Elliott, Prof. J. A. Nixon, Prof. Adam Patrick, Dr. W. N. West Watson. Hon. Secretaries: Dr. James Lindsay, 1, The Circus, Bath; Dr. F. G. Chandler, 1, Park-square West, Portland-place, London, N.W. 1.

Provisional Programme.—July 22nd.—Discussion: Rheumatoid Arthritis, its Causation and Treatment. To be opened by Sir Humphry Rolleston, followed by Dr. Rupert Waterhouse (Treatment), Sir Robert Jones (Surgical), Dr. J. M. H. Monro (Bacteriology), Mr. A. G. Timbrell Fisher (Pathological), Mr. W. R. Ackland (Dental), and Sir William H. Willcox.

July 23rd.—Discussion: Hyperpiesia. To be opened by Lord Dawson; followed by Prof. E. H. Starling, Dr. H. Batty Shaw, Dr. Otto May, and Dr. Geoffrey Evans.

July 24th.—Discussion: The Uses and Abuses of Endocrine Therapy. To be opened by Dr. W. Langdon Brown and Prof. Swale Vincent; followed by Dr. H. Gardiner-Hill, Mr. Kenneth M. Walker, Dr. H. W. C. Vines, and Prof. F. S. Langmead.

Surgery.

President: Sir Berkeley Moynihan. Vice-Presidents: Mr. A. H. Burgess, Mr. Frederick Lace, Mr. H. S. Souttar, Mr. C. F. Walters. Hon. Secretaries: Mr. A. de V. Blathwayt, 6, Brock-street, Bath; Mr. A. L. Fuller, 9, Gay-street, Bath; Mr. R. M. Vick, 152, Harley-street, London, W. 1.

Provisional Programme.—July 22nd.—Discussion: Carcinoma of the Stomach. To be opened by Sir W. I. de Courcy Wheeler; followed by Dr. E. I. Spriggs (Clinical Manifestations and Early Diagnosis), Dr. A. F. Hurst (Auxiliary Methods of Diagnosis, Radiological and Chemical), Prof. M. J. Stewart (Pathology: General Relation of Carcinoma to Ulcer; Mode of Spread and Frequency of Secondary Deposits in Liver), Mr. J. Sherren, Mr. John Morley, Dr. J. A. Nixon, and Mr. A. H. Burgess.

July 23rd.—Discussion: Acute Intestinal Obstruction. To be opened by Sir William Taylor; followed by Mr. W. Sampson Handley and Mr. D. P. D. Wilkie. A general report and statistics from various hospitals for the past five years will be presented by Mr. H. S. Souttar (London Hosp.), Mr. R. P. Rowlands (Guy's), Mr. C. Max Page (St. Thomas's), Mr. R. M. Vick (St. Bartholomew's), Mr. L. R. Braithwaite (Leeds), Mr. G. Grey Turner (Newcastle), Mr. A. H. Burgess (Manchester), Mr. A. Rendle Short (Bristol), and Mr. A. B. Mitchell (Belfast).

July 24th.—Combined discussion with Orthopædic Section: Treatment of Fractures, with special reference to its Organisation and Teaching. To be opened on the Surgical side by Mr. G. E. Gask; followed by Mr. S. W. Daw, Mr. H. Wade, Mr. H. H. Sampson, and Mr. A. W. Sheen; and on the Orthopædic side by Sir Robert Jones; followed by Dr. R. Osgood (Boston, U.S.A.), Mr. H. Platt, Mr. H. A. T. Fairbank, Mr. C. Max Page, and Mr. Gwynne E. O. Williams.

Obstetrics and Gynæcology.

President: Lady Barrett. Vice-Presidents: Mr. H. S. Davidson, Mr. Eardley L. Holland, Mr. W. F. Rawson, Mr. D. C. Rayner. Hon. Secretaries: Mr. W. H. Duncan, 13, Gay-street, Bath; Dr. J. Bright Banister, 19, Harley-street, London, W. 1.

Provisional Programme.—July 22nd.—Discussions: (*a*) The Problems of Uterine Cancer. To be opened by Prof. B. P. Watson. (*b*) The Surgical Treatment of Malignant Disease of the Pelvic Organs. To be opened by Mr. Victor Bonney and Mr. S. J. Cameron. The following will take part in the discussions: Prof. C. Oldfield, Mr. H. J. D. Smythe, Dr. R. S. S. Statham, and Prof. W. C. Swayne.

July 23rd.—Discussion: The Treatment of Inoperable Cancer of the Pelvic Organs. To be opened by Dr. James Heyman (Stockholm); followed by Mr. Percival P. Cole and Mr. Malcolm Donaldson. Paper: Dr. D. C. Hare: Preliminary Investigation into the Circulatory Changes in Normal Pregnancies.

July 24th.—Discussion: The Rôle of Surgery in the Treatment of Backward Displacement of the Uterus. To be opened by Miss M. H. Frances Ivens; followed by Dr. H. Russell Andrews, Prof. J. M. Munro Kerr, Mr. R. H. Paramore, Mr. D. C. Rayner, Mr. D. Shannon, and Sir Henry J. F. Simson.

Pathology and Bacteriology.

President: Prof. J. C. G. Ledingham. Vice-Presidents: Dr. J. A. Braxton Hicks, Prof. E. H. Kettle, Dr. Rupert Waterhouse. Hon. Secretaries: Lieut.-Colonel James Cowan, 44, Combe-park, Bath; Dr. C. C. Okell, Wellcome Physiological Research Laboratories, Langley Court, Beckenham, Kent.

Provisional Programme.—July 22nd.—Discussion: Filter-passing Viruses. To be opened by Dr. W. E. Gye; followed by Mr. J. E. Barnard, Dr. Mervyn H. Gordon, Dr. S. P. Bedson, and Dr. J. E. McCartney.

July 23rd.—Discussion: The Pathological Basis of Treatment by Radiation. To be opened by Prof. S. Russ; followed by Dr. T. S. P. Strangeways, Miss M. E. Hume, and Dr. A. Piney.

July 24th.—Discussion: The Present Position of Pathology and Bacteriology in this Country, with special reference to Research. To be opened by the President of the section.

Neurology and Psychological Medicine.

President: Sir Maurice Craig. Vice-Presidents: Prof. Edwin Bramwell, Dr. Arthur F. Hurst, Dr. Norman Lavers, Dr. S. A. K. Wilson. Hon. Secretaries: Dr. Ray Edridge, 29, Gay-street, Bath; Dr. Edward Mapother, Maudsley Hospital, Denmark Hill, London, S.E. 5.

Provisional Programme.—July 22nd.—Discussion: Causation and Symptomatology of Multiple Neuritis. To be opened by Dr. T. Grainger Stewart; followed by Dr. James S. Collier, Dr. Wilfred J. Harris, Dr. W. Johnson, and Dr. F. J. Nattrass.

July 23rd.—Discussion: Treatment of Insomnia. To be opened by Dr. Robert Hutchison; followed by Dr. Harry Campbell, Dr. Henry Devine, and Dr. C. P. Symonds.

July 24th.—Discussion: Prophylaxis of Mental Disorder. To be opened by Sir Humphry Rolleston; followed by Dr. A. Helen A. Boyle, Dr. Bernard Hart, Dr. Edward Mapother, and Dr. T. A. Ross.

Therapeutics (including Balneology and Radiotherapy).

President: Prof. R. B. Wild. Vice-Presidents: Dr. Preston King, Dr. W. Mitchell, Dr. Nathan Mutch. Hon. Secretaries: Dr. Cecil H. Terry, 15, The Circus, Bath; Dr. Dorothy C. Hare, 1, Bickenhall Mansions, London, W. 1.

Provisional Programme.—July 22nd.—Discussion: Treatment of Asthma. To be opened by Dr. W. Langdon Brown, followed by Dr. E. P. Poulton, and Dr. P. Hamill.

July 23rd.—Discussion: Treatment of Chronic Arthritis. To be opened by Sir Thomas Horder; followed by Dr. Preston King (Balneology), Dr. N. Mutch, and Dr. C. B. Heald.

July 24th.—Discussion: Therapeutic Value of Light. To be opened by Prof. W. E. Dixon; followed by Dr. C. E. M. Jones (Clinical) and Dr. G. H. Lancashire. Paper: Dr. Newman Neild: The Uses of Posture for Bronchial Drainage,

Laryngology, Otology, and Rhinology.

President: Mr. Arthur H. Cheatle. Vice-Presidents: Mr. Neil Maclay, Dr. Irwin Moore, Mr. Sydney R. Scott. Hon. Secretaries: Mr. H. N. Barnett, 27, The Circus, Bath; Dr. R. Scott Stevenson, 30, New Cavendish-street, London, W. 1.

Programme.—July 22nd.—Discussion: Overlooked Cases of Foreign Body in the Air and Food Passages. To be opened by Prof. Chevalier Jackson (Philadelphia); followed by Dr. Thomas McCrae (Philadelphia), Sir StClair Thomson, and others. Prof. Chevalier Jackson: (*a*) Demonstration on the Extraction of Foreign Bodies from the Air and Food Passages; (*b*) Cinematographic demonstration of Bronchoscopic Aspiration for Suppurative Diseases of the Lung of other than Foreign Body Origin. Dr. T. McCrae: Bronchoscopy for Disease. Mr. V. E. Negus: Evolutionary Factors in Causation of Pharyngeal Diverticula. Dr. Irwin Moore: An Outline of the History of Endoscopy.

July 23rd.—Discussions: (1) Operative Treatment of Chronic Middle-ear Suppuration. To be opened by Mr. G. J. Jenkins; followed by Mr. Sydney R. Scott, Mr. J. S. Fraser, and Mr. J. Bowring Horgan. (2) Treatment of Chronic Non-suppurative Middle-ear Deafness (excluding Oto-sclerosis). To be opened by Sir William Milligan; followed by Dr. J. Kerr Love, Sir Robert Woods, Mr. Neil Maclay, and Mr. H. Norman Barnett.

July 24th.—Discussion: Occupational Diseases of Ear, Nose, and Throat, and their Prevention. To be opened by Mr. F. H. Westmacott; followed by Surgeon-Commander S. W. Grimwade, Wing-Commander D. Ranken, Mr. T. Jefferson Faulder, Mr. C. A. Scott Ridout, and Mr. T. Ritchie Rodger.

The following Sections will each meet on two days:—

Diseases of Children.

President: Dr. Robert Hutchison. Vice-Presidents: Dr. Carey F. Coombs, Mr. P. T. Crymble, Dr. Charles McNeil, Dr. Reginald H. Miller. Hon. Secretaries: Dr. Vincent Coates, M.C., 10, The Circus, Bath; Mr. R. A. Ramsay, 123, Gloucester-terrace, Hyde Park, London, W. 2.

Provisional Programme.—July 22nd.—Joint discussion with the Section of Public Medicine: Rheumatic Infection in Childhood—Early Diagnosis and Preventive Treatment. To be opened by Dr. F. J. Poynton and Dr. R. A. Askins (M.O.H. Bristol); followed by Dr. Carey F. Coombs, Dr. Reginald Miller, Dr. J. A. Glover (Ministry of Health), and Dr. Vincent Coates.

July 23rd.—Discussion: Treatment of Empyema. To be opened by Dr. H. C. Cameron and Mr. H. S. Souttar; followed by Dr. F. G. Chandler, Mr. H. W. C. Romanis, and Mr. T. Twistington Higgins.

Ophthalmology.

President: Dr. W. Marlon Beaumont. Vice-Presidents: Dr. R. Wallace Henry, Mr. A. W. Ormond, Mr. C. H. Walker. Hon. Secretaries: Dr. R. Colley, 30, The Circus, Bath; Mr. P. G. Doyne, 8, Harley-street, London, W. 1.

Provisional Programme.—July 22nd.—Discussion: Eye Injuries and Interstitial Keratitis. To be opened by Mr. W. T. Holmes Spicer.

Papers: Mr. A. W. Ormond, Visual Hallucinations of Sane People. Mr. N. Bishop Harman: Phlyctenular Conjunctivitis and Keratitis—Causes and Prevention. Dr. R. Wallace Henry: Instrument for Recording Light Minimum and Light Difference. Dr. R. Colley: Case of Perforating Wound of Eye with Retention of Piece of Glass.

July 23rd.—Discussion: Ocular Pain. To be opened by Mr. A. Freeland Fergus.

Papers: Mr. C. H. Walker: Amaurosis. Mr. Lindsay Rea: Treatment of Ocular Syphilis. Mr. J. Burdon-Cooper: Conservative Treatment of Glaucoma.

Orthopædics.

President: Prof. E. W. Hey Groves. Vice-Presidents: Dr. Naughton Dunn, Mr. G. R. Girdlestone, Mr. E. Muirhead Little. Hon. Secretaries: Dr. J. S. Levis, M.C., 20, Gay-street, Bath; Mr. T. Twistington Higgins, 27, Harley-street, London, W. 1.

Provisional Programme.—July 23rd.—Discussion: Tuberculous Disease of the Spine. To be opened by Prof. Calvé (Paris); followed by Mr. G. R. Girdlestone, Mr. W. T. G. Pugh, and Mr. James Russell.

July 24th.—Joint discussion with Section of Surgery on the Treatment of Fractures, with special reference to Organisation and Teaching. (See above.)

Public Medicine.

President: Dr. T. Eustace Hill. Vice-Presidents: Dr. T. W. Naylor Barlow, Dr. J. F. Blackett, Dr. W. A. Brend, Dr. S. Noy Scott. Hon. Secretaries: Dr. R. E. Thomas, 11, Darlington-place, Bath; Dr. A. Neville Cox, 21, Cornwall-gardens, Preston Park, Brighton.

Provisional Programme.—July 22nd.—Joint discussion with the Section of Diseases of Children: *Rheumatic Infection in Childhood—Early Diagnosis and Preventive Treatment.* To be opened by Dr. F. J. Poynton (Children's Section) and Dr. R. A. Askins, School Medical Officer and M.O.H. Bristol (Public Medicine Section).

July 23rd.—Discussions: (1) Food Manipulation in Relation to Health. To be opened by Dr. W. G. Savage. Dr. C. E. Goddard will speak with special reference to Accidental Contamination. (2) Influence of Sunlight and *Artificial Lights on Health, including Smoke Pollution.* To be opened by Dr. Leonard Hill; followed by Dr. G. B. Dixon, who will speak particularly on the *Influence of* Light on Tuberculosis, and Dr. Dora C. Colebrook.

The following Section will meet on one day:—

Medical Sociology.

President: Dr. Charles E. S. Flemming. Vice-Presidents: Dr. J. W. Bone, Mr. Wilfred Buckley, Mr. G. P. Male, Dr. E. A. Starling. Hon. Secretaries: Dr. C. A. Marsh, The Roseries, Englishcombe, Bath; Dr. C. J. Buchan, 326, Brownhill-road, Catford, London, S.E. 6.

Provisional Programme.—July 24th.—Morning.—Discussion: What should be the Standard of Purity of Milk? To be opened by Dr. R. Stenhouse Williams, from the point of view of the bacteriologist; Dr. W. G. Savage, from the *point of view of the medical officer of health; and Dr. Eric* Pritchard, from the point of view of the dietist. Afternoon.—Discussion: By What Means can Pure Milk be Obtained, and the Cost? To be opened by Mr. Wilfred Buckley (National Clean Milk Society), as a producer; Mr. G. P. Male, as a veterinary surgeon; and Mr. J. H. Maggs (chairman, United Dairies), as a distributor. Two films will be shown with the following titles: *Production of Certified* Milk on an English Farm, and Handling and Distribution of Milk in New York City.

THE BRITISH SOCIAL HYGIENE COUNCIL

(LATE NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES).

THE British Social Hygiene Council held their tenth annual meeting on July 9th in the Robert Barnes Hall of the Royal Society of Medicine. Sir Auckland Geddes delivered the presidential address.

Annual Meeting.

The President, in his opening remarks, paid a tribute to his predecessor, Lord Trevethin, who had done so much to combat venereal disease. He went on to point out the unusual interest of the occasion; the Council was now looking back over 11 years of activity and difficulty during which great progress had been made. Between the years 1920 and 1924 the numbers of new cases of syphilis at the treatment centres had fallen from 48,000 to 22,000, while the number of attendances had risen from under 1,500,000 to 1,645,000. It was clear from these figures and others that venereal disease had been combated in this country with increasing success, though the end was not yet in sight. The British Social Hygiene Council, coöperating with the Ministry of Health and the local authorities, had done a great deal towards this result. In order to determine the aims of the Council for the future it was necessary to consider what the reduction of venereal disease would mean not only for the present generation but for posterity. The figures quoted showed that the number of new infections had definitely diminished, so that every unborn child had a proportionately *greater chance of escaping infection.* The Council looked forward over a vast field of effort, and while *they saw clearly that medical work against venereal* disease was profoundly important and was progressing rapidly, yet the *problem* had many other aspects. There was no group of diseases in which medical, social, and moral problems were *so inextricably* interwoven, and medicine could not achieve victory over venereal disease *by itself.* The change in their title showed that the Council had greatly enlarged their scope and they now aimed to preserve and strengthen the family. It was very necessary in these days to impress upon the conscience of the people that the family was the basic social unit. No one who took thought for the future of the country could fail to realise that the foundation of its greatness was the health of its stock, and so the British Social Hygiene Council appealed to all the citizens of the Empire and of other countries to secure that future generations should be uncontaminated by a preventable and curable disease.

The Council aimed at promoting a high standard of sex conduct. Sexual morality was closely connected with housing, and the horrible conditions under which human beings were herded together went far to explain the present low standard of morality. The Council joined hands with all who worked to improve the conditions of life, housing, recreation, and the whole environment of those who were compelled from poverty to live under conditions sometimes too dreadful to describe. The medical attack must be strong, thorough, and frank, but they would have to make every effort to improve the lives of the people.

The Viscount Illingdon, a Vice-President of the Council, and Chairman of the Indian Council, pleaded for an extension of their work in the British Empire and particularly in India, which contained three-quarters of the Empire's population and where the high incidence of venereal disease was very serious. He thanked the Indian Medical Services for the work they had done in fighting venereal disease in India and hoped that the Government departments would assist in every possible way to eliminate it, though he realised that they had to contend with great difficulties.

Mrs. Garlin Spencer, a Director of the Board of the American Social Hygiene Association, described the evolution of similar social work in America.

Official Banquet.

In the evening a dinner was held at the Hotel Cecil to celebrate the successful results of 11 years' work and to initiate the broader policy. After the loyal toasts had been honoured the health of the British Social Hygiene Council was proposed by Lord Merrivale, President of the Divorce Court, who spoke of the "conspiracy of silence" which had surrounded the "social evil" in his youth and of the courage with which the present generation was breaking that silence and attacking that evil. He saw in this new attitude, reflected in the new name of the Council, a possibility of success that had not existed in the old days.

Sir Auckland Geddes, responding to the toast, recalled the national stocktaking in the days of the war and the realisation of the heavy toll venereal disease was then taking of the country's health, strength, and vitality.

The health of the guests was proposed by Mr. Greaves Lord, K.C., M.P., in the absence of Mr. J. Wheatley, M.P. He said that the greatness of England depended on the performance by each generation in turn of its duty to posterity, and no greater work for the future could be found than that of the Council of Social Hygiene.

Surgeon Vice-Admiral J. Chambers, Medical Director-General of the Navy, in responding, gave a brief account of the very successful results of instruction in the home water fleet and the great fall in the incidence of venereal disease in the mercantile marine. The reports from foreign waters, especially the Far East, were less satisfactory.

The toast of the "Associated Organisations" was proposed by Mrs. Scharlieb, M.D., who described the correlation of the work in England, America, Canada, Australia, and South Africa. Mrs. Scandrett (South Africa), Mrs. Anna Garlin Spencer (America), and Dr. Kendal Bates (Canada) replied, and the proceedings concluded with the health of the President, proposed by Mr. E. B. Turner.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

The sixth annual general meeting of the Society for the Prevention of Venereal Disease was held at 12, Stratford-place on July 8th. The President of the Society, Sir Auckland Geddes, occupied the chair, and said there had been a very great reduction in venereal disease, amounting to nearly 50 per cent., within the last five years. He did not think any one organisation could claim that this reduction was the result of their labours alone, for all who had taken part in attempting to educate the people as to the importance and dangers of venereal disease and in teaching the public how to prevent the disease might say they had contributed to this great improvement. He said that he believed that fusion between the British Social Hygiene Council and the Society for the Prevention of Venereal Disease was undesirable because, although both the societies had accepted the Trevethin report, they had accepted it with quite different emphasis laid upon the different recommendations. He thought that when dealing with such a subject as venereal disease it was inevitable that those at the one extreme of thought would find it impossible to understand the point of view of those at the other extreme of thought, although both extremes and those between them were working for the same end. He considered that the Society for the Prevention of Venereal Disease had got hold of a very important part of the work which has to be done. What they desired to see was that the causal organisms of the different diseases should be destroyed whenever and wherever they might be found, and that this matter should be dealt with unsentimentally, and though there was a wide field for coöperation with those who laid the emphasis on the moral and emotional side, an attempt to get all who are working for the prevention of venereal disease into one society would result in a great loss. In the belief that the continuance of the two organisations is good and that it is really better than fusion, he had, after careful consideration, accepted the position of President not only of this Society but of the other society, believing that in that way, although the societies continued as separate and independent bodies, it would be possible to present a united front to the Government or the Department of State concerned. He thought that it would be wise for the Society to concentrate upon getting a definite reply from the Ministry of Health in the coming months, and he proposed that the resolution before the meeting should be laid before the Government in the autumn in the following terms:—

> "That this meeting with great respect urges the Government to give effect without further delay to the recommendations contained in the Trevethin Report, which the Minister of Health has stated have been accepted in principle, and further begs to call the attention of the Minister of Health to the resolution submitted to the Ministry of Health at the annual general meeting of the Society in July, 1924, requesting the allocation to the Society for the Prevention of Venereal Disease of an equitable proportion of any sum set aside for the education of the public regarding venereal disease and its prevention, to which no reply has yet been received."

Mr. Wansey Bayly, honorary secretary of the Society, reported the work of the Society during the past year, and said that a new situation had arisen owing to Sir Auckland Geddes having accepted also the presidency of the British Social Hygiene Council, but their Society would do their best to help him in this new situation. Important progress had been gained during the last year by Sir Auckland Geddes's double appointment and by the acceptance of the principle of immediate self-disinfection by the British Social Hygiene Council. He added that the Ministry of Health had acknowledged that the evidence of witnesses before the Trevethin Committee was available for reference or publication.

Mr. Harry Machin presented the financial report and annual audit.

Lady Askwith, in seconding the resolution, said she thought many of the members of the Society would agree that Sir Auckland Geddes was right in maintaining that fusion between the two societies was not possible or desirable, and she was also sure that there would be nobody who did not feel perfectly safe in the hands of Sir Auckland Geddes as President of both organisations.

Mr. Basil Peto, M.P., in supporting the resolution, expressed his pleasure in hearing that the President had also taken the position of President of the other society, and he entirely agreed with the conclusion reached that fusion would not have been a source of strength, but the best possible liaison between the two societies was to have one head for both. It was, he reminded the audience, two years since the committee presided over by Lord Trevethin reported, but no steps had been taken to carry out what their Society regarded as the most important part of the report, that dealing with the sale of the necessarily simple preventive disinfectants at chemists' shops.

Mr. A. J. Bennett, M.P., said that the Society could not expect to obtain all their revenue from a very limited number of persons, and that it was only right they should try to get funds from the public.

The resolution was put to the meeting and carried unanimously.

CONVENTION OF ENGLISH-SPEAKING OPHTHALMOLOGICAL SOCIETIES,

LONDON, JULY 14TH–17TH.

OPENING SESSION.

THE formal opening of the Convention took place in the Memorial Hall, University College, on Tuesday morning, when speeches were delivered by Mr. Neville Chamberlain, Minister of Health, and Mr. Houghton, the American Ambassador.

Addresses of Welcome.

The Minister of Health first referred to the hiatus produced in the holding of large, and especially international, congresses by the Great War, and said that though the members of this Congress would regret the absence of the wider scope and the more varied treatment which would be derived from the attendance of delegates from all over the world, there was some compensation in the fact that the language which would be used would be understood by all. He alluded with satisfaction to the striking advances which had been made in ophthalmology in the last 70 years, particularising the discoveries relating to the powers of accommodation and the accuracy of the instruments now available. He also referred to the great attention being given to the eyesight of children, and the energy with which ophthalmic clinics, 482 in number, were being conducted. Such attention was increasingly necessary with the ever augmented stress and hustle of the life of cities. He warmly commended the spirit which had resulted in the organisation of this Congress, and which would bring about improved knowledge in regard to the preservation of the function of the most precious of all the special senses.

The American Ambassador (Mr. Houghton) expressed, on behalf of the American visitors, appreciation of the welcome which had been accorded them by the Minister of Health, and humorously warned his compatriots to beware of the elaborate hospitality prepared for them by the organisers of the Convention. He also affected an anxiety about the welfare of the population of the States with so many of the country's eye surgeons in a foreign land.

The following representatives of visiting bodies were then presented to Mr. Chamberlain, and delivered short speeches expressing the satisfaction which it gave them to be present: Dr. G. E. de Schweinitz (American Ophthalmological Society), Dr. W. R. Parker (Ophthalmological Section of the American Medical Association), Dr. L. M. Francis (American Academy of Ophthalmology and Oto-Laryngology), Dr. W. G. M. Byers (Montreal Ophthalmological Society), and Dr. A. J. Hall (New Zealand Branch of the British Medical Association).

Presentations.

The President, in presenting the Nettleship Prize to Prof. S. E. Whitnall, of Montreal, for his monumental work on the anatomy of the orbit, said Edward Nettleship and Sir William Bowman both left deep footprints in the sands of time. In memory of the latter had been established the Bowman Lecture, and to commemorate the name of Nettleship his friends had established a prize for the encouragement of ophthalmic work, to be awarded triennially. It was, the President said, a great pleasure to him that Prof. Whitnall had been able to come from Montreal to receive the award at his hands.

Prof. Whitnall, in a few words of thanks, said it was a real pleasure to him to be able to renew friendships which were formed in the early days of the Oxford ophthalmological congresses, where the friendly talks on ophthalmological subjects were the mainsprings of any subsequent work he felt called upon to do in relation to the eye.

Mr. W. T. Holmes Spicer then presented to the President the Critchett Memorial Presidential Badge. It was, he said, Sir Anderson Critchett's father, George Critchett, who lived through the great time of ophthalmological discovery and research, that blossoming time when the ophthalmoscope was discovered, and father and son had together practised the specialty for nearly 100 years, probably a record of its kind. George Critchett was not a prolific writer; his chief energies were clinical, and the devising of operations for various ocular conditions. Sir Anderson Critchett was born in an atmosphere in which he might be said to have lisped ophthalmology. But he had the disadvantage in early years of a divided allegiance, for he was devoted to music and was the possessor of a fine voice, hence his singing was in great request. There came a time when his father told him he must make his choice; he must either be a singer or a surgeon, and the world knew what the choice was. To his credit it must be said that though formerly he was continually singing at concerts, when he decided on his life's career he never sang again in public. Mr. Spicer paid a high tribute to Sir Anderson Critchett's fine qualities, social and professional, and then invested the President with the badge, beautifully worked in gold, and bearing portraits of George and Anderson Critchett, with a Latin inscription. He wished the President a long life and a continuation of the fine work which he had been doing during the last forty years.

THE PRESIDENT'S ADDRESS.

The Elimination of Eye Disease.

Mr. Treacher Collins then delivered his presidential address. His purpose, he said, was simply to present a few historic facts which, aided by imagination, would enable a peep to be taken through a hole in the curtain of the present and gaze at some wonders that might come to pass. For the elimination of disease it was essential to know everything concerning the working mechanism of the organism and the varying conditions of its environment; and owing to recent work it had now become possible to contemplate the elimination of some eye diseases in the human organism. In *leprosy* the eyes were frequently affected and the sight destroyed. Probably many cases of the disease were brought there by the returning Knights Templar and their retinue, among whom lack of cleanliness was regarded as a virtue. To the segregation of the affected was probably due the absence of more serious spread. But there were still 300,000 cases of leprosy in the British Empire.

With regard to *small-pox* three-fourths to one-half of the indigent blind applying for relief in the last century in this country lost their sight through this disease, but in 1922 the Departmental Committee on the causes and prevention of blindness could only discover six cases due to it in asylums for the blind.

title showed that the Council had greatly enlarged their scope and they now aimed to preserve and strengthen the family. It was very necessary in these days to impress upon the conscience of the people that the family was the basic social unit. No one who took thought for the future of the country could fail to realise that the foundation of its greatness was the health of its stock, and so the British Social Hygiene Council appealed to all the citizens of the Empire and of other countries to secure that future generations should be uncontaminated by a preventable and curable disease.

The Council aimed at promoting a high standard of sex conduct. Sexual morality was closely connected with housing, and the horrible conditions under which human beings were herded together went far to explain the present low standard of morality. The Council joined hands with all who worked to improve the conditions of life, housing, recreation, and the whole environment of those who were compelled from poverty to live under conditions sometimes too dreadful to describe. The medical attack must be strong, thorough, and frank, but they would have to make every effort to improve the lives of the people.

The Viscount Illingdon, a Vice-President of the Council, and Chairman of the Indian Council, pleaded for an extension of their work in the British Empire and particularly in India, which contained three-quarters of the Empire's population and where the high incidence of venereal disease was very serious. He thanked the Indian Medical Services for the work they had done in fighting venereal disease in India and hoped that the Government departments would assist in every possible way to eliminate it, though he realised that they had to contend with great difficulties.

Mrs. Garlin Spencer, a Director of the Board of the American Social Hygiene Association, described the evolution of similar social work in America.

Official Banquet.

In the evening a dinner was held at the Hotel Cecil to celebrate the successful results of 11 years' work and to initiate the broader policy. After the loyal toasts had been honoured the health of the British Social Hygiene Council was proposed by Lord Merrivale, President of the Divorce Court, who spoke of the "conspiracy of silence" which had surrounded the "social evil" in his youth and of the courage with which the present generation was breaking that silence and attacking that evil. He saw in this new attitude, reflected in the new name of the Council, a possibility of success that had not existed in the old days.

Sir Auckland Geddes, responding to the toast, recalled the national stocktaking in the days of the war and the realisation of the heavy toll venereal disease was then taking of the country's health, strength, and vitality.

The health of the guests was proposed by Mr. Greaves Lord, K.C., M.P., in the absence of Mr. J. Wheatley, M.P. He said that the greatness of England depended on the performance by each generation in turn of its duty to posterity, and no greater work for the future could be found than that of the Council of Social Hygiene.

Surgeon Vice-Admiral J. Chambers, Medical Director-General of the Navy, in responding, gave a brief account of the very successful results of instruction in the home water fleet and the great fall in the incidence of venereal disease in the mercantile marine. The reports from foreign waters, especially the Far East, were less satisfactory.

The toast of the "Associated Organisations" was proposed by Mrs. Scharlieb, M.D., who described the correlation of the work in England, America, Canada, Australia, and South Africa. Mrs. Scandrett (South Africa), Mrs. Anna Garlin Spencer (America), and Dr. Kendal Bates (Canada) replied, and the proceedings concluded with the health of the President, proposed by Mr. E. B. Turner.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

THE sixth annual general meeting of the Society for the Prevention of Venereal Disease was held at 12, Stratford-place on July 8th. The President of the Society, Sir Auckland Geddes, occupied the chair, and said there had been a very great reduction in venereal disease, amounting to nearly 50 per cent., within the last five years. He did not think any one organisation could claim that this reduction was the result of their labours alone, for all who had taken part in attempting to educate the people as to the importance and dangers of venereal disease and in teaching the public how to prevent the disease might say they had contributed to this great improvement. He said that he believed that fusion between the British Social Hygiene Council and the Society for the Prevention of Venereal Disease was undesirable because, although both the societies had accepted the Trevethin report, they had accepted it with quite different emphasis laid upon the different recommendations. He thought that when dealing with such a subject as venereal disease it was inevitable that those at the one extreme of thought would find it impossible to understand the point of view of those at the other extreme of thought, although both extremes and those between them were working for the same end. He considered that the Society for the Prevention of Venereal Disease had got hold of a very important part of the work which has to be done. What they desired to see was that the causal organisms of the different diseases should be destroyed whenever and wherever they might be found, and that this matter should be dealt with unsentimentally, and though there was a wide field for coöperation with those who laid the emphasis on the moral and emotional side, an attempt to get all who are working for the prevention of venereal disease into one society would result in a great loss. In the belief that the continuance of the two organisations is good and that it is really better than fusion, he had, after careful consideration, accepted the position of President not only of this Society but of the other society, believing that in that way, although the societies continued as separate and independent bodies, it would be possible to present a united front to the Government or the Department of State concerned. He thought that it would be wise for the Society to concentrate upon getting a definite reply from the Ministry of Health in the coming months, and he proposed that the resolution before the meeting should be laid before the Government in the autumn in the following terms:—

> "That this meeting with great respect urges the Government to give effect without further delay to the recommendations contained in the Trevethin Report, which the Minister of Health has stated have been accepted in principle, and further begs to call the attention of the Minister of Health to the resolution submitted to the Ministry of Health at the annual general meeting of the Society in July, 1924, requesting the allocation to the Society for the Prevention of Venereal Disease of an equitable proportion of any sum set aside for the education of the public regarding venereal disease and its prevention, to which no reply has yet been received."

Mr. Wansey Bayly, honorary secretary of the Society, reported the work of the Society during the past year, and said that a new situation had arisen owing to Sir Auckland Geddes having accepted also the presidency of the British Social Hygiene Council, but their Society would do their best to help him in this new situation. Important progress had been gained during the last year by Sir Auckland Geddes's double appointment and by the acceptance of the principle of immediate self-disinfection by the British Social Hygiene Council. He added that the Ministry of Health had acknowledged that the evidence of witnesses before the Trevethin Committee was available for reference or publication.

Mr. Harry Machin presented the financial report and annual audit.

Lady Askwith, in seconding the resolution, said she thought many of the members of the Society would agree that Sir Auckland Geddes was right in maintaining that fusion between the two societies was not possible or desirable, and she was also sure that there would be nobody who did not feel perfectly safe in the hands of Sir Auckland Geddes as President of both organisations.

Mr. Basil Peto, M.P., in supporting the resolution, expressed his pleasure in hearing that the President had also taken the position of President of the other society, and he entirely agreed with the conclusion reached that fusion would not have been a source of strength, but the best possible liaison between the two societies was to have one head for both. It was, he reminded the audience, two years since the committee presided over by Lord Trevethin reported, but no steps had been taken to carry out what their Society regarded as the most important part of the report, that dealing with the sale of the necessarily simple preventive disinfectants at chemists' shops.

Mr. A. J. Bennett, M.P., said that the Society could not expect to obtain all their revenue from a very limited number of persons, and that it was only right they should try to get funds from the public.

The resolution was put to the meeting and carried unanimously.

CONVENTION OF ENGLISH-SPEAKING OPHTHALMOLOGICAL SOCIETIES,

LONDON, JULY 14TH–17TH.

OPENING SESSION.

THE formal opening of the Convention took place in the Memorial Hall, University College, on Tuesday morning, when speeches were delivered by Mr. Neville Chamberlain, Minister of Health, and Mr. Houghton, the American Ambassador.

Addresses of Welcome.

The Minister of Health first referred to the hiatus produced in the holding of large, and especially international, congresses by the Great War, and said that though the members of this Congress would regret the absence of the wider scope and the more varied treatment which would be derived from the attendance of delegates from all over the world, there was some compensation in the fact that the language which would be used would be understood by all. He alluded with satisfaction to the striking advances which had been made in ophthalmology in the last 70 years, particularising the discoveries relating to the powers of accommodation and the accuracy of the instruments now available. He also referred to the great attention being given to the eyesight of children, and the energy with which ophthalmic clinics, 482 in number, were being conducted. Such attention was increasingly necessary with the ever augmented stress and hustle of the life of cities. He warmly commended the spirit which had resulted in the organisation of this Congress, and which would bring about improved knowledge in regard to the preservation of the function of the most precious of all the special senses.

The American Ambassador (Mr. Houghton) expressed, on behalf of the American visitors, appreciation of the welcome which had been accorded them by the Minister of Health, and humorously warned his compatriots to beware of the elaborate hospitality prepared for them by the organisers of the Convention. He also affected an anxiety about the welfare of the population of the States with so many of the country's eye surgeons in a foreign land.

The following representatives of visiting bodies were then presented to Mr. Chamberlain, and delivered short speeches expressing the satisfaction which it gave them to be present: Dr. G. E. de Schweinitz (American Ophthalmological Society), Dr. W. R. Parker (Ophthalmological Section of the American Medical Association), Dr. L. M. Francis (American Academy of Ophthalmology and Oto-Laryngology), Dr. W. G. M. Byers (Montreal Ophthalmological Society), and Dr. A. J. Hall (New Zealand Branch of the British Medical Association).

Presentations.

The President, in presenting the Nettleship Prize to Prof. S. E. Whitnall, of Montreal, for his monumental work on the anatomy of the orbit, said Edward Nettleship and Sir William Bowman both left deep footprints in the sands of time. In memory of the latter had been established the Bowman Lecture, and to commemorate the name of Nettleship his friends had established a prize for the encouragement of ophthalmic work, to be awarded triennially. It was, the President said, a great pleasure to him that Prof. Whitnall had been able to come from Montreal to receive the award at his hands.

Prof. Whitnall, in a few words of thanks, said it was a real pleasure to him to be able to renew friendships which were formed in the early days of the Oxford ophthalmological congresses, where the friendly talks on ophthalmological subjects were the mainsprings of any subsequent work he felt called upon to do in relation to the eye.

Mr. W. T. Holmes Spicer then presented to the President the Critchett Memorial Presidential Badge. It was, he said, Sir Anderson Critchett's father, George Critchett, who lived through the great time of ophthalmological discovery and research, that blossoming time when the ophthalmoscope was discovered, and father and son had together practised the specialty for nearly 100 years, probably a record of its kind. George Critchett was not a prolific writer; his chief energies were clinical, and the devising of operations for various ocular conditions. Sir Anderson Critchett was born in an atmosphere in which he might be said to have lisped ophthalmology. But he had the disadvantage in early years of a divided allegiance, for he was devoted to music and was the possessor of a fine voice, hence his singing was in great request. There came a time when his father told him he must make his choice; he must either be a singer or a surgeon, and the world knew what the choice was. To his credit it must be said that though formerly he was continually singing at concerts, when he decided on his life's career he never sang again in public. Mr. Spicer paid a high tribute to Sir Anderson Critchett's fine qualities, social and professional, and then invested the President with the badge, beautifully worked in gold, and bearing portraits of George and Anderson Critchett, with a Latin inscription. He wished the President a long life and a continuation of the fine work which he had been doing during the last forty years.

THE PRESIDENT'S ADDRESS.

The Elimination of Eye Disease.

Mr. Treacher Collins then delivered his presidential address. His purpose, he said, was simply to present a few historic facts which, aided by imagination, would enable a peep to be taken through a hole in the curtain of the present and gaze at some wonders that might come to pass. For the elimination of disease it was essential to know everything concerning the working mechanism of the organism and the varying conditions of its environment; and owing to recent work it had now become possible to contemplate the elimination of some eye diseases in the human organism. In *leprosy* the eyes were frequently affected and the sight destroyed. Probably many cases of the disease were brought there by the returning Knights Templar and their retinue, among whom lack of cleanliness was regarded as a virtue. To the segregation of the affected was probably due the absence of more serious spread. But there were still 800,000 cases of leprosy in the British Empire.

With regard to *small-pox* three-fourths to one-half of the indigent blind applying for relief in the last century in this country lost their sight through this disease, but in 1922 the Departmental Committee on the causes and prevention of blindness could only discover six cases due to it in asylums for the blind.

Much of this improvement was due to the greater care now paid to the eyes in critical pyrexial diseases, as well as to the reduction in the number of cases of small-pox.

Speaking of *ophthalmia*, Mr. Collins mentioned the work done on the modes of transference of the disease. The causal organisms did not produce spores, and drying killed them, hence infection was only likely to occur while the eyes were in a moist state. No specific microbe had been identified with the worst form of ophthalmia—namely, trachoma—but it was probable that this virus also was killed by drying; and general measures based on this had largely eliminated this disease from the British Army and from the Poor-law schools of London, where at one time it was rife. A tribute to the cleanliness of the modern British soldier was that the Egyptian Expeditionary Force fought its way along the same route as did the trachoma-infested Napoleonic troops without contracting it, but when large numbers of Turks were taken prisoner they were found to be severe sufferers from trachoma with corneal complications. At an inspection made by Nettleship of the Poor-law schools of London in 1874, 42 per cent. were found to have granular lids or trachoma, but in 1896 Sydney Stephenson found the figure reduced to 4·91 per cent. The disease was virulently contagious, and liable to rapid spread in favouring conditions.

The protean manifestations of *syphilis* were one of the commonest causes of eye disease in this country; the departmental committee already referred to considered that from 10 per cent. to 15 per cent. of the blindness of the country was due to this disease. Mr. Collins did not share a hopeless view as to the elimination of syphilis among the community; in this contest between man and the spirochæte the odds were undoubtedly on man. An encouraging stage was reached when the appointment of the Royal Commission on the subject broke down the conspiracy of silence which until then had surrounded it. In 1920 105,185 infected people presented themselves at the official treatment centres, and in 1923 the number had declined to 73,013; and a similar fall had occurred in other countries where similar facilities were provided. He thought that in respect of the wilful transfer of these diseases to others the punishment should be made to fit the crime—namely, incarceration and treatment until the convicted person could be declared free from the infection.

Concerning *iritis* in the last 25 years a great change of view as to the ætiology had taken place. What had been described as "rheumatic iritis" was very rarely associated with acute articular rheumatism; the commonest form of joint affection found in association with iritis was gonorrhœal, a disease which was present in 15 per cent. of the cases.

The recognition of *metastatic septic infection* as a cause of iritis was largely due to the work of Mr. William Lang, who found that in 37 per cent. of his cases of iritis pyorrhœa was the sole ascertainable cause; certainly rapid recovery of the iritis followed removal of the affected foci, no other treatment but heat and atropine having been used. If more mouths were kept clean and if it was realised that a gold-crowned tooth could harbour bad septic foci, the total amount of intra-ocular inflammation would be materially reduced.

It was not possible to say as a result of statistics whether *tuberculous* eye disease was diminishing, but both here and in America there had been noted a steady reduction in the amount of respiratory tuberculosis, and the death-rate from it showed a bigger drop than in any other period of which there were authentic records. He alluded to the great improvement in the condition of cases of tuberculous eye disease when they were removed from their homes to Swanley Ophthalmia Schools, and this he attributed to the sunshine and out-of-door life, and the good food and ample playing spaces.

The elimination of *phlyctenular* ophthalmia and keratitis was a social problem, being bound up with over-population and living in congested conditions. He referred to the importance of the diet including fat-soluble A vitamin, especially in the obviation of xerophthalmia and keratomalacia, the latter, however, being but a rare disease in this country.

Certain *hereditary diseases of the eye* seemed to be chiefly due to a tissue degeneration; such was retinitis pigmentosa, a condition which was very resistant to every known treatment. And it was regrettable that the parents suffering from this disease were the reverse of sterile. It would be a proper course to advise sufferers who had married to refrain from bearing progeny.

Myopia Mr. Collins considered to be largely the outcome of our present system of education. It seemed altogether unnatural that the young growing (human) animal should be compelled to spend hours daily poring over books, often in artificial light, and educational authorities were remarkably slow in taking advantage of other educative means, such as the epidiascope, oral teaching to a greater extent, broadcasting, and the use of the lantern. Lessons in geography, for instance, could be converted into a veritable voyage of discovery for the young mind.

In conclusion the President referred to the work which had been done in the seven years of its existence by the Council of British Ophthalmologists, which was formed to assist Government Departments and other persons in regard to its special subject. The United States now had a parallel body with very similar aims. He also referred to the work of the new International League of Red Cross Societies, and to that done by the Health Department of the League of Nations, the latter having conducted investigations likely to have far-reaching results. Disease, he said, was the common foe of all nations, and active coöperation on the part of all of them was required in order to build up a more moral, more intellectual specimen of *Homo sapiens* than that now striding the earth, pluming himself on being the lord of creation.

BRITISH EMPIRE CANCER CAMPAIGN.

ANNUAL MEETING.

The second annual report of the Grand Council of the British Empire Cancer Campaign was presented by the chairman, Viscount Cave, at a meeting held at the House of Lords on Monday, July 13th, when a message was read from the Duke of York, President of the Campaign, wishing success to its labours. The campaign, which came into existence in the spring of 1923, has had at its disposal a sum of just over £100,000, which has enabled the Council to assist existing cancer research institutions to maintain their work at maximum efficiency as well as to initiate and devise fresh lines of research. A concerted effort is being made to obtain trustworthy statistics of cancer from outlying parts of the Empire. Help is being freely given to expensive and difficult research in connexion with the causation and treatment of cancer by means of radium, X and other rays, carried on jointly with the Radiology Committee of the Medical Research Council. Radium to the value of £5000 has been purchased and put at the disposal of this joint committee, while the Radon Centre at the Middlesex Hospital has undertaken the production and supply of radium emanation. Lord Cave concluded his review of the year's activities with the warning that only by continuous and patient effort can knowledge be increased and results achieved. At the Council meeting which followed Dr. J. A. Murray, of the Imperial Cancer Research Fund, and Lieut.-Colonel A. B. Smallman, secretary to the Departmental Committee on Cancer, were invited to join the Intelligence Committee of the Campaign.

The report contains a summary of the work of the various committees of the Campaign. During the year the Financial Committee announces an income from donations and collections of £31,168, plus £2600 bank interest, out of which £2380 have been used up in administration and £3361 in appeals, a percentage—

be it noted—of only 9·2 of the total funds raised during the period. £280 have gone to travelling and incidental expenses of committees and lecturers, while grants for research work have totalled £10,170. Grants are made on the recommendation of a Scientific Advisory Committee appointed jointly by the Royal Society, the Medical Research Council, and the Cancer Campaign. Institutions have benefited as follows: £3725 to the Medical Research Council (Radon Centre at Middlesex Hospital), £6900 to the Middlesex Hospital (Cancer Research Department), £5000 to the Cancer Hospital Research Institute, £1095 to St. Bartholomew's Hospital (Radiological Cancer Research Department), £1000 to Christie Hospital, Manchester, £600 to St. Mark's Hospital, London, £200 to Coombe Lying-in Hospital, Dublin, £1500 to the Tropical Disease Prevention Association, and £5000 to the purchase of 800 mg. of radium for cancer research divided between St. Bartholomew's Hospital, St. Peter's Hospital, and the Medical Women's Federation. Individual grants have been made to Dr. Thomas Lumsden (Lister Institute), Dr. Malcolm Donaldson, Dr. Louis Sambon, Dr. J. C. Mottram (Radium Institute), and Mr. I. Hieger, B.Sc. (Cancer Hospital Research Department).

A notable change has been effected in the organisation of cancer research at the Middlesex Hospital, where the scientific departments have been invited to initiate cancer research along their own special lines under the supervision of Prof. J. McIntosh (pathology), Prof. S. Russ (physics), and Prof. E. C. Dodds (biochemistry). At the Cancer Hospital a scheme of work has been initiated under the five headings of: (1) experimental production, (2) clinical and surgical pathology, (3) immunity experiments, (4) experiments in chemotherapy, (5) statistical inquiries. An interesting research has been in progress to test the effect of prolonged administration of food preservatives on animals; so far small amounts of boron, tin, and copper oft repeated have had no appreciable ill effect on mice and rats. At St. Bartholomew's Hospital a special X ray research department has been set apart for investigating malignant disease of the breast, the upper air passages and pharynx, and the uterus. At Manchester a local cancer committee will shortly take over the general management of research in the various institutions; a questionnaire has been issued in order to trace the history of all cancer patients in the city. At St. Mark's Hospital the outcome of some recent work suggests the important part played by lymphoid follicles of the intestine in the protection of the body against cancer. Dr. Lumsden's work at the Lister Institute on an antiserum, selective for particular cancer cells, is familiar to our readers and is being continued. The grant to the Tropical Disease Prevention Association for investigation of cancer in relation to parasites carries the proviso that cancer material, both animal and human, and specimens of parasites shall be brought back to this country for investigation.

The report, which contains much else of interest, bears striking testimony to the wide range of inquiry instituted by the British Empire Cancer Campaign, the address of which is 19, Berkeley-street, London, W. 1.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his successful appeal and to make good the deficiency in his professional income. Accordingly the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Already received and acknowledged ..	493	3	0
Drs. Gerrard, Bickford, and Cloake ..	3	3	0
Dr. E. W. Dewey	1	1	0
Dr. Mary Kidd	0	10	0
Dr. Mohammed Eid.	0	10	0

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Heart Cinematography.

PHYSICIANS are finding that disorder of rhythm is an increasingly valuable guide in the diagnosis and treatment of heart trouble, and its value is proportioned to the accuracy with which it can be observed. Auscultation is useful, but some method of recording the movements is essential for precise observation. The thoracic cage hides a living heart from sight, and few practitioners have time to study artificial contractions in the laboratory. Mr. Lutembacher's method of filming the isolated and perfused heart therefore fills a pressing need. He has already used his device to show his students the more common rhythmic disorders and to help them to understand the electro-cardiographic curves taken at the same time as the moving photograph. The next step is to use this method to examine the direct action of cardiac remedies. Marey has already used it to observe the contraction of voluntary muscles.

Narcotic Poisoning.

Dr. Ch. Achard recently reported to the Academy of Medicine five cases of suicidal narcotic poisoning of which two were fatal. Four were due to dial and one, which recovered, to veronal. A clinical phenomenon worthy of note was the very marked muscular hypotonus observed in these cases, contrasting with the brisk reflexes, Babinski's sign even being obtained. In one case catatonic attitudes appeared; in another a syndrome recalling that of disseminated sclerosis, slurring speech, ataxia, fine intention tremor, and nystagmus; in a third case the pupils were fixed. The growing frequency of these cases of poisoning proves the necessity for regulating the sale of narcotic drugs.

The Efficacy of Vaccination and the Virulence of Small-pox.

Dr. Alcay, of Nimes, has just published some important statistics of the epidemic of small-pox in Switzerland in 1921. The form of the infection was mild and vaccination was completely protective. The German cantons, where vaccination is voluntary, were all swept by the disease, those where it is obligatory escaped altogether. Emergency vaccination measures were successful in stamping out the epidemic wherever they were applied. Such evidence of the value of compulsory vaccination ought to have persuaded the Federal Council to impose it on the whole country, but the Government, remembering the difficulties encountered in a similar attempt in 1882, and also considering the mildness of the infection, only ordered vaccination for certain groups of the population. These half measures cost Switzerland several thousands of sick people and a few deaths, but the results would have been very grave if the epidemic had had the usual severity of small-pox.

Dr. A. Netter has recently drawn the attention of the Academy of Medicine to the frequency of small-pox and the tendency of the disease to take a benign form. The condition seemed about to disappear from civilised countries, but during the last few years has shown an unexpected recrudescence, particularly in Switzerland and England. In the former country only 14 cases were registered between 1915 and 1920, but the numbers rose abruptly to 596 in 1921, 1150 in 1922, and 2145 in 1923. They fell again in 1924 to 1245, and in the first five months of 1925 to 150. In England and Wales 7 cases were recorded in 1917 and 63 in 1918. In 1919, 1920, and 1921 there were 311, 280, and 330 cases respectively; in 1922 there were 973, in 1923 2054, and in 1924 3395. Already 3008 notifications have been received for 1925. In both these countries anti-vaccination influence has been at work. In Switzerland it has succeeded in removing the regulation of vaccination from the hands of the Federal Government to the cantonal authorities.

Since 1888 there has been no compulsory vaccination in most of the German cantons, and these cantons showed (from 1921–23) a small-pox incidence of 1910 per 1000, while the incidence in the French cantons was 24. Although the number of cases has increased so greatly the number of deaths, always less than 1 per cent., has dropped sometimes to less than 1 per 1000. Small-pox has lost its virulence; even among the non-vaccinated it is milder than it used to be among the vaccinated.

The American Medical Week in Paris.

Nearly 500 physicians and surgeons from the United States and Canada, many of them accompanied by their wives, are now visiting the hospitals and laboratories of Paris. The week was inaugurated in the great amphitheatre of the Faculty of Medicine, under the presidency of Mr. Herriot, President of the Chamber of Deputies, supported by Dr. Charles Mayo, of Rochester, and Mr. Peck, of Chicago. Among those present on the platform were the Minister of Public Instruction and of Hygiene, the Director of Higher Education, the Rector of the University of Paris, the Dean of the Faculty, and Mr. Tuffier, President of the organisation committee. Many congratulatory speeches were made. On leaving the building the members of the congress proceeded to the Arc de Triomphe to pay homage at the tomb of the unknown warrior. In the afternoon there was a reception at the Hôtel de Ville, when Mr. Guillaumin, President of the Municipal Council, conveyed a welcome from the City of Paris.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Prof. Bier on Homœopathy.

Prof. Bier, the celebrated surgeon of Berlin, has caused a considerable sensation in medical circles by an article to the *Münchener Medicinische Wochenschrift*, in which he recommended the study of homœopathy. He said that the homœopathic doctrine had in some respects proved true; the treatment of inflammation by artificial congestion instead of the application of cold devised by himself and counter-irritation, therapy were based on the theory of *similia similibus*. He had himself lately found that bronchitis caused by the administration of ether could be successfully treated by subcutaneous injections of ether; the application of hot air to a burn produced a rapid development of new epithelium. With regard to homœopathic dosage of certain substances, he had found from personal experience that one drop of iodine dissolved in a glass of water would abort the colds to which he himself was liable. In his hospital furunculi were treated with very small doses of sulphur, whereas it was known that large doses produced furunculi. Hahnemann's advice to ascertain the reaction of a healthy person to a certain remedy before deciding on the dosage in any disease he thought quite reasonable. Prof. Bier's manifesto was received enthusiastically by the medical and lay adherents of homœopathy. The homœopathic journals reproduced it with sensational headings such as "celebrated professor converted to homœopathy" or "Hahnemann's works recommended by University Professor," &c. Copies of the article were distributed in meetings of the homœopathic societies and the homœopaths renewed their old demand that chairs of homœopathy be instituted at the universities. The medical press, commenting on the whole affair, stated that by reopening a discussion which had apparently been closed many years ago Prof. Bier had done great damage, especially to the younger generation, whose therapeutical views were not quite settled. To combat that damage the *Münchener Medicinische Wochenschrift* published a reply to Prof. Bier by Prof. Henbuer, the well-known Professor of Pharmacology at Göttingen University; the *Deuts* *edizinische Wochenschrift* reprinted articles w ppeared in former issues by the late Prof alin with that question. The Berlin Society for Internal Medicine convoked a medical meeting in the Langenbeck-Virchow House, Prof. His being in the chair. The great assembly hall was crowded as never before, more than 1200 medical men and women being present. Strict control was carried out at the entrance to prevent laymen from entering, the daily papers having drawn the attention of the public to the meeting. Before the meeting Prof. Müller, of Marburg, gave a report of the history of homœopathy, Prof. Heubner, of Göttingen, spoke on the differences between the dogma of homœopathy and experimental natural science. In the discussion Prof. Bier said that medicine was more than a natural science; it ought to be regarded as an art where intuition is essential. Medicine had often been advanced by the intuition of men of genius, even if their views had not been in accordance with natural science. According to him, Hahnemann was such a genius, although his works must be regarded as a mixture of the highest wisdom and the greatest folly. He had expected to be severely attacked by his professional brethren. He was far from being converted to homœopathy, as had been suggested both in the press and in letters received by him, but he only wished to draw attention to the fact that there was some truth in homœopathy. It was useless to treat its adherents with contempt, rather should harmony be brought about between homœopathy and allopathy. With the exception of some homœopaths, all the speakers combated Prof. Bier's views. The meeting lasted about four hours and ended late in the night.

Lawsuits between Medical Men and Locum Tenents.

The great medical union known as the Hartmann-Bund, formerly Leipziger Verband, provides its members with locum tenents in cases of absence or illness, a work done in England by private medical agencies. Candidates to such posts had to subscribe a declaration that they would abstain for a couple of years from settling in the town or district of their employer. This declaration led in many instances eventually to lawsuits where it was not observed by the locum tenens, who settled down in his former employer's neighbourhood and did him grave damage. Law courts had given different verdicts in the matter, some stating that such declarations were not in accordance with the law, whilst others had found for the plaintiffs. By a recent judgment of the High Court of Justice the matter is now definitely settled. It is decided that the declaration must be regarded as illegal; as the medical profession is a scientific institution controlled and protected by the State for the welfare of the population, members of that profession cannot be denied the exercise of their calling through private agreements on merely economical grounds. This judgment is obviously not in accordance with the present economical condition of the profession. Doctors must have recourse to such private agreements in order to protect their economical interests, although they were blamed in so doing by the High Court. Medical men do not see the meaning of "State protection" in a country where anybody is allowed to give medical advice and charge fees for it without being medically qualified provided he does not make use of a recognised medical title.

Doctors' Income-tax.

In a recent leading article in THE LANCET, entitled "Penalising Medical Efficiency,"[1] it is stated that according to a decision of the High Court a county medical officer is not entitled to deduct the amount of his subscriptions to medical societies from his income-tax assessment. It may be of interest to English readers to learn what the law and the regulations are in Germany concerning the items to be deducted by a medical man. The German High Court has lately decided that every expense which served to keep a medical man abreast with new scientific research and to increase his knowledge in order to apply new methods of treatment may be deducted. Those expenses include subscriptions to medical journals, membership of medical societies, travels to medical congresses, and post-graduate courses. A certain amount may be deducted annually for the amortisation of the cost of a medical library. According to a later decision the subscriptions, but curiously not the entrance fees, to professional societies having no scientific but only economical aims are deductible. Like other professional men a medical man is entitled to deduct from his net income that part of his house rent which covers the rooms used solely for the conduct of his practice—viz., the consulting and the waiting-room and the expenses for heating and lighting them, the depreciation of furniture, of instruments, and the telephone. If a servant is employed exclusively for the conduct of practice, the total salary may be deducted; if the servant does other housework also, a part of it only. The expenses entailed in keeping a carriage, a motor, or a bicycle together with the salary of the driver or chauffeur are also exempt, and it does not matter if the medical man uses those vehicles occasionally for non-professional purposes, it being supposed that he would not have bought them except as a help in his practice. During the time of the depreciation of the currency, when it was impossible to fix those expenses, medical men had to deduct 25 per cent. of their net income for "professional expenses."

---

[1] THE LANCET, June 6th, p. 1191.

Syphilis of the Stomach.

At a recent meeting of the Berlin Surgical Society Dr. Rumpel reported cases of gummata in the stomach lately operated on by him. He stated that such cases were very rare. Several forms of syphilitic affections of the stomach must be distinguished: (*a*) Gastritis with thickening of the wall of the stomach, caused by a proliferation of the submucosa; (*b*) gummata, multiple or single, which might become ulcerous and, like other ulcers, might lead to hæmorrhage and to perforation. The syphilitic ulcers, he said, had a smooth base covered with lardaceous matter. A reliable diagnosis was very difficult, but when symptoms of gastric ulcer were present without increase of gastric acid, syphilitic ulcer might be suggested. The administration of salvarsan was of no value for the diagnosis. In one instance the diagnosis had been made previous to the operation. Dr. Rumpel had operated upon two cases where, when the stomach had been opened a growth like cancer was found which on microscopical examination proved to be gumma. In the discussion Dr. Nordmann reported that he had operated upon three cases; a phlegmonous infiltration of the surroundings of the ulcers seemed to be characteristic. Two of his cases died, the other recovered, but afterwards died from aneurysm.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 4TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 66; scarlet fever, 1563; diphtheria, 830; enteric fever, 43; pneumonia, 690; puerperal fever, 39; cerebro-spinal fever, 5; acute poliomyelitis, 6; encephalitis lethargica, 57; continued fever, 3; dysentery, 4; ophthalmia neonatorum, 119. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 6 deaths from enteric fever, 51 from measles, 10 from scarlet fever, 65 from whooping-cough, 21 from diphtheria, and 30 from influenza. In London itself there were no deaths from influenza; deaths from whooping-cough numbered 12, and from diphtheria 5.

BOTANIC LABORATORY FOR BEDFORD COLLEGE.—The new Sargant Laboratory of Plant Physiology at Bedford College for Women, the only one of its kind in London, was opened on July 9th by Lord Justice Sargant. The money for the laboratory was bequeathed by his sister, the late Miss Alice Sargant, who was formerly a student and ardent admirer of Bedford College. The laboratory has a botanic garden attached to it.

Correspondence.

"Audi alteram partem."

THE RIVER AMAZON FOR TOURISTS.

To the Editor of THE LANCET.

SIR,—In the last few years the attractions of the Amazon have begun to interest a considerable number of tourists, and to those who have never visited this section of Brazil the trip from Pará to Manáos cannot fail to be of interest.

It has come to my notice that some British practitioners, on being consulted by their patients as to the advisability of making this trip, give warnings of the Amazon being a region of yellow fever, malaria, and swamps. In all justice to the Federal and State authorities such statements should be contradicted. Yellow fever became extinct in Pará after the anti-yellow fever campaign of Oswaldo Cruz in 1911, and the State of Amazonas has been recorded clean since the end of 1913.

When I arrived in Manáos in 1905 the situation was vastly different; then it was the case that most of the newly-arrived foreigners sooner or later suffered from "yellow jack"—I was an early victim—and malaria was rife all over the town. To-day all is changed and the tourist no longer excites the wonder of the Manauense, nor is the commercial traveller considered to be a brave man for venturing so far up the Amazon. It is a difficult matter, however, to eradicate the old idea of the Amazon being a death's hole; but the health of the foreigner is excellent, and I have only a couple of cases of malaria a year to deal with. Malarial fevers are common, certainly, but they are contracted in regions which the tourists never visit.

Manáos is only about 3·40 metres above sea-level and lies in lat. 3° 08′ 30″, and long. 59° 59′ 27″ west of Greenwich. The temperature, while not high for the tropics, is very constant and ranges between 75° and 95° F. in the hot season and 68° and 86° F. in the cooler months; the relative humidity is 63 per cent. to 70 per cent. The temperature in Pará is rather lower and there is more breeze. Both cities were provided with all modern advantages when the "black gold" of the Amazon (rubber) commanded high prices and favourable exchange, and, consequently, the drainage and water systems are good; there are excellent tramways and all the comforts of electric lighting and ventilating. Pará possesses a modern and cool hotel.

It is a matter of regret that more medical men do not visit this country of Wallace, Bates, and Spruce, for it is full of interest. I believe Sir John Bland-Sutton enjoyed his visit, although he did far more sightseeing and observing than the ordinary tourist. I think it would be wise to advise patients to wear clothing suitable for the warmer climate of the tropics—sun helmets are not required—and to keep to a hot weather dietary. This advice is necessary when they leave Pará for the trip up the Amazon to Manáos and encounter a greater humidity as well as leading a sedentary life for the four days on board ship until they arrive at Manáos and can step ashore at a miniature Liverpool landing stage for exercise and sightseeing. I do not recommend pulmonary tuberculosis cases making the tour, and patients with very high blood pressure should be warned not to exert themselves unduly during the hotter part of the early afternoon.

I am, Sir, yours faithfully,

H. WOLFERSTAN THOMAS,

Manáos Research Laboratory, Liverpool School of Tropical Medicine.

June 8th, 1925.

*** We may remind intending tourists of the promising field offered by the Amazon Valley for finding new drugs, *videlicet* annotation in our issue for July 4th.—ED. L.

THE PURSUIT OF PURE MILK.

To the Editor of THE LANCET.

SIR,—No one who has any knowledge of the conditions under which milk is produced, distributed, and consumed in this country can dispute the general conclusions of your article on "The Pursuit of Pure Milk." May I be allowed, however, as chief chemist and bacteriologist of the distributing firm responsible for the large portion of London's milk-supply, to controvert a suggestion contained in your remarks on pasteurisation, which may prove misleading. "The basal fact," says your article, "is that at the present time the bulk of the milk consumed in the large towns is pasteurised by processes which are uncontrolled as regards the temperatures reached or the time the milk is held at a high temperature." The implication here and in succeeding sentences is that pasteurisation is a purely casual process of heating, and the phrase "controlled pasteurisation," a few lines lower down in the article, is used seemingly as a synonym for "scientific pasteurisation," as distinct from the commercial significance of the term.

I should like to state categorically that the suggestion, so far as concerns the plants controlled by the United Dairies, Ltd., is entirely unjustified. The milk distributed by the firm's associated companies is pasteurised under a system of control which ensures its being submitted to an even temperature of 145° F. for half an hour. In their plants the holding tanks are provided with an automatic temperature recorder, which affords incontestable proof of the constancy of the heat to which the milk is subjected. An automatic device provides for the release of the milk from the tank at the end of half an hour.

Moreover, our inspectors conduct frequent examinations of the plants to ensure the cleanliness of the apparatus, and samples are taken at every stage of the process.

Milk can be made clean and safe by means of filtration, clarification, and pasteurisation, but milk producers in this or any other country have not yet reached that state of idealistic perfection when clean production will obviate the necessity for these dairy processes.

Until we reach this Utopian state of affairs, pasteurisation is the only method of maintaining a milk-supply which can be truthfully described as "safe." In fact, in such advanced dairying countries as Denmark, Sweden, and many of the United States of America, pasteurisation is compulsory.

It may remain questionable whether in the process of pasteurisation something is lost of the nutritive qualities of the milk, though my own researches have led me to the conclusion that the loss is negligible. What is beyond question is that safety—i.e., freedom from pathogenic organisms—must be our first consideration. In this connexion, with the coöperation of Prof. R. T. Hewlett, of London University, who is consulting bacteriologist to United Dairies, Ltd., I have conducted a series of tests over a period of many months with the most encouraging results. In every case where milk samples (taken from herds in all parts of the country and not from cows especially inoculated for our purposes) have been found tuberculous before pasteurisation, no trace of infection remained after the process.

United Dairies are doing their utmost in all ways to encourage healthy herds and clean production on the farms, but, of necessity, the bulk of this important work must fall to the Ministries of Agriculture and Health.

I may add that Prof. Hewlett desires me to say that he associates himself with all I have said in this letter.

I am, Sir, yours faithfully,
J. D. ROBERTS.

Analytical and Bacteriological Laboratories,
35, Little Russell-street, London, W.C.,
July 7th, 1925.

*** Our remarks referred to milk consumed in the large towns, not specifically to London, and we have yet to learn that the holder system of pasteurisation is applied throughout the country. The essential point is that, apart from control by Government regulation, it is open to anyone who supplies milk to alter the temperature to be employed or the length of time during which it is maintained, or to use or not to use a holder type of pasteuriser. The milk is not sold as "pasteurised" milk and therefore is not subject to inspection by the Ministry or the local authority. Such pasteurisation can properly be spoken of as uncontrolled. The effect of pasteurisation in retarding efforts to obtain a clean milk-supply is adequately dealt with by Dr. Savage in his special article.—ED. L.

THE ATTRACTIONS OF THE ROYAL NAVAL VOLUNTEER RESERVE.

To the Editor of THE LANCET.

SIR,—May I ask your assistance in calling the attention of the younger members of the medical profession to the attractions offered by service in the Royal Naval Volunteer Reserve?

The R.N.V.R. consists of seven divisions: London, Scottish, Tyne, Mersey, Bristol, Sussex, and Ulster. The establishment provides for 205 medical officers; of whom 50 are on List I. and the remainder on List II., and in addition 28 dental surgeons. Each category has to serve 28 days at sea during their first year of service and subsequently 14 days biennially either afloat in one of H.M. ships or in a naval hospital or depôt. Those on List I. have in addition to attend periodically at the headquarters of the division to which they are attached for the examination of recruits and other medical duties. The age of entry is from 21 to 32 years. Provision is also made for the entry as surgeon sub-lieutenants of students from 19 to 26 years who have passed their intermediate examination in anatomy and physiology. Promotion is on the same basis as in the Royal Navy except that no examinations are held. During training medical officers receive the naval pay of their rank, and £50 is provided for the expenses of uniform on joining, or, in the case of probationary officers, on confirmation in rank.

The service affords a unique opportunity for seeing the life of the Royal Navy, as well as providing every two years a most interesting experience free of all expense and well paid for the duties required, whether afloat or ashore. Applications for commissions should be addressed to the commanding officer at the headquarters of the nearest division, from whom full particulars can be obtained.

I am, Sir, yours faithfully,
J. BRUCE RONALDSON,
Surgeon-Commander, R.N.V.R.

H.M.S. *President*, Victoria Embankment, E.C. 4,
July 13th, 1925.

PRELIMINARY TRAINING IN DOMESTIC ARTS, KING'S COLLEGE HOSPITAL.

To the Editor of THE LANCET.

SIR,—Twelve months ago THE LANCET kindly expressed an interest in the establishment of a course of domestic arts in connexion with the preliminary training school which was opened at the beginning of September. Perhaps you will allow me to report upon the points upon which some doubt was expressed. It has been proved quite clearly that the two sets of pupils have been, in the American phrase, which you quoted, "good mixers." Those who have taken the course without any idea of becoming nurses have taken a keen interest in the scientific, practical, and domestic sides of the course, and their influence has been distinctly helpful.

The suggestion that the pupils would be taking the place of paid domestic help in the pupil nurses' home is one which is not supported in fact. All pupils, whether nurse pupils or not, have certain duties to perform under supervision as part of their training; that is part of the curriculum and without it the course could hardly be said to fulfil its function. Paid domestic help is made use of for those parts of the work which it is neither desirable nor helpful for the pupils to carry out, and the amount and expense of such assistance employed are increased by every additional pupil, whether she be in training for the nursing school or not.

THE LANCET made a somewhat cruel insinuation against the girl of the present day in suggesting that the opportunity to appreciate some of the joy of service would have no attraction for her. The opportunity to see something of the work of the hospital and the privilege, which also THE LANCET doubted, of taking some part in its work, have, in fact, been greatly appreciated by the pupils, and have, it is believed, exerted a beneficial influence on those who have undertaken the course.

I am, Sir, yours faithfully,

C. E. A. BEDWELL,
House Governor.

July 13th, 1925.

*** We are happy to publish Mr. Bedwell's letter. The annotation will be found in THE LANCET of 1924, ii., 504, under the title "Housewifery in a Hospital Milieu" and Mr. Bedwell does not reproduce the words we used.—ED. L.

Obituary.

ALEXANDER JOSEPH McAULEY BLAYNEY, F.R.C.S.IREL.,

SURGEON TO THE MATER MISERICORDIÆ HOSPITAL, DUBLIN.

THE tragically sudden death of Mr. Alexander Blayney on Sunday last, July 12th, has caused deep grief in the medical profession of Dublin and Ireland. He had recently had an attack of influenza, and while walking with his wife and children across the Portmarnock golf links, he suddenly fell to the ground. Medical aid was to hand at once, but death had apparently been instantaneous. He was 56 years of age.

Alexander Blayney was born in Co. Antrim and educated in Belfast and in the Catholic University, Dublin. He had a distinguished career in the Royal University, winning, among other honours, the studentship in biology. He took his medical degrees in 1893, and became a Fellow of the Royal College of Surgeons in Ireland in 1898. He held for a time the chair of Biology in University College, Dublin, but his bent was toward surgery, and early in his career he became one of the surgical staff of the Mater Misericordiæ Hospital. Since the foundation of the National University in 1908 he was assistant to the professor of surgery in the Dublin College. He was a Member of Council of the Royal College of Surgeons in Ireland for many years past and could easily have reached higher honours in the College had he sought them. He held, from time to time, examinerships both in the Royal College of Surgeons and in Trinity College, Dublin. During the war he served in the 83rd (Dublin) General Hospital, with the rank of major.

For many years past Mr. Blayney had one of the largest operating and consulting practices in Ireland. He had a wide and accurate knowledge of his subject, and was endowed with a judicious mind and even temper, with the result that his diagnosis was careful and sound, and very rarely was he led into error. In operation he was cool and resourceful. Any practitioner who once sought his help in a difficult case rarely thought of looking for another surgeon ever after. Though his ability as a surgeon was recognised by both the profession and the public, Mr. Blayney never took the prominent position in the profession to which his talents entitled him. He sought retirement and avoided publicity. He never sought the chair of his College in spite of the pressure of his friends, but it was understood that he would in the near future have allowed his name to go forward. Apart from his profession he was a man of wide reading and much culture, loving literature, music, golf, bridge, and conversation. Reserved with strangers, and always modest and retiring, something more than a casual acquaintance was required to discover the fund of humanity, humour, and wisdom that lay behind his quiet manner. His death was so sudden and unexpected that in the sense of the loss of a loved friend his colleagues cannot yet realise how much Irish surgery has suffered.

JOSEPH BOWER SIDDALL, M.D. ABERD.

Dr. Joseph Bower Siddall, who died at Great Malvern on July 4th, at the age of 85, was in the real sense of the word a pioneer of medicine, for in 1868 he went to Japan as medical officer to H.B.M.'s Legation. There, in association with the late Dr. Willis, he had charge of the Japanese hospitals in Yokohama, and later in Yedo (now Tokio) during the War of the Restorature in 1868–69. He established the first hospital, called the Dai Biyoin (or the Great Hospital) in Yedo in 1868, where he accomplished his cherished aim of introducing hygienic methods into the Japanese military service. He put his experience on record in an article published in Vol. V. of St. Thomas's Hospital Reports. He so forcibly advocated the value of vaccination in Japan that the Mikado issued an order that the whole of the population was to be vaccinated, with the result that in 15 years small-pox was virtually stamped out. Previously no measures had been adopted to combat this disease, which was very rife. For his services to Japan he was awarded the Order of the Rising Sun by the Mikado, but it was not until 1900 that he received the permission of the British Foreign Office to wear the Order. He had the distinction of being the first foreigner to receive it. Dr. Siddall was a fine cricketer in his day, and his golf-handicap was four. He played cricket for the Gentlemen of England, and as he stood 6 ft. 2 in., and was broad in proportion, he was naturally a hard hitter. He was proud of the fact that he had smashed the clock at the Oval; he occasionally played in the same eleven as the "Three Graces." At the Royal North Devon Golf Club, of which he was one of the founders, he used to tell how Mr. J. H. Taylor as a boy acted as his caddy. Dr. Siddall qualified from St. Thomas's Hospital in 1864 as M.R.C.S. Eng. and L.S.A. He afterwards went to Aberdeen, where he took the M.D. with highest honours.

On his return from Japan he practised for a time at Ross-on-Wye, retiring about 35 years ago to reside in Devonshire and latterly in Malvern. Dr. Siddall married Mary Elizabeth, second daughter of Charles Binns, J.P., of Claycross Hall, Chesterfield, who predeceased him some years ago.

HAROLD CLIFFORD, M.B. LOND., F.R.C.S. EDIN.

Dr. Clifford, whose death took place at his residence, St. John-street, Manchester, on July 8th, was well known as a gynæcologist. Son of the late Dr. John Clifford, the veteran Baptist preacher, Dr. Clifford settled in Manchester 25 years ago after taking a medical course at University College, London, where he was house physician at the hospital. Qualifying in 1897, he took the M.B. Lond. in 1899 and the F.R.C.S. Edin. in 1905. He was connected with the staff of St. Mary's Hospital for many years, and since 1913 was honorary surgeon and gynæcologist at the Royal Salford Hospital. He lectured on clinical obstetrics at the Victoria University of Manchester, and was an external examiner in midwifery at Queen's University, Belfast. Dr. Clifford had been in indifferent health for some months, but his death was sudden and took his many friends by surprise.

Parliamentary Intelligence.

HOUSE OF LORDS.

THURSDAY, JULY 9TH.

Mental Deficiency Bill.

THE Mental Deficiency Bill was read a second time. This Bill has already passed through the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, JULY 8TH.

Vaccination and Chicken-pox.

Mr. **BROMFIELD** asked the Minister of Health whether, in view of the difficulties which existed in regard to the diagnosis of mild small-pox and chicken-pox, he would give instructions, in cases where chicken-pox was made a notifiable disease, for the condition of the patients as regards vaccination to be stated on the form of notification, with a view to statistical records being inserted in the annual reports of the medical officers of health showing the total number of vaccinated and unvaccinated chicken-pox cases notified in each year.—Sir **KINGSLEY WOOD** (Parliamentary Secretary to the Ministry of Health) replied: The answer is in the negative. My right hon. friend is advised that a mere statement on the notification form as to the vaccinal condition of such patients would not be of any material assistance in arriving at an accurate diagnosis, and as it has never been suggested that vaccination affords any protection against chicken-pox, he does not consider that statistical records as to the vaccinal condition of patients suffering from that disease would be of value.

THURSDAY, JULY 9TH.

Provision of Massage for Disabled Men.

Captain **BOWYER** asked the Minister of Pensions whether in future he would utilise the services locally in rural areas of qualified masseurs and masseuses for the treatment of disabled men, and thus save the time of the men and unnecessary suffering to the disabled.—Major **TRYON** replied: It is the experience of the Ministry that massage is most effectively administered in the interests of patients when carried on at a clinic under proper medical supervision. Where, however, this treatment can be efficiently administered otherwise, and attendance at a clinic would involve serious inconvenience and hardship to the patient, alternative arrangements are allowed.

Distribution of Health Insurance Surpluses.

Sir **HENRY CAUTLEY** asked the Minister of Health under what authority and for what reason he prohibited approved societies from distributing the surpluses, over and above the requisite reserves, disclosed by the recent valuations in extra cash benefits in excess of 5s. for sickness benefit; and whether, considering the difficulty in devising schemes for other benefits in the case of the small societies such as those in the Sussex County Association, he would allow all the surpluses, except requisite reserves, to be distributed in extra cash benefits.—Mr. **NEVILLE CHAMBERLAIN** replied: In accordance with a decision of the National Health Insurance Joint Committee, approved societies have been recommended in the interests of their members not to adopt extra cash benefits in excess of 5s. a week for sickness benefit unless they are also making reasonably adequate provision for treatment benefits. Schemes complying with the latter condition, and providing for an increase of over 5s. in sickness benefit, have already been sanctioned for several societies, including three that are constituent societies of the Sussex County Association. It will be seen, therefore, that there has not been a general prohibition of the kind suggested in the question.

Extension of Health Insurance Membership.

Mr. **DENNISON** asked the Minister of Health the number of insured persons who were unable to claim the extension of National Health Insurance membership under The Prolongation of Insurance Act, 1921, owing to the fact that they had not paid the necessary contributions in the two contribution years ending July, 1920, or in any other respects had not complied with the statutory conditions of the Act; and if such persons would be disqualified from claiming the benefits in accordance with the provisions of the Widows', Orphans', and Old Age Contributory Pensions Bill.—Mr. **NEVILLE CHAMBERLAIN** replied: Cessation of insurance, otherwise than by death, may be due to a variety of causes, and particulars are not available at headquarters to show, with regard to the members of between 8000 and 9000 approved societies and registered branches, how far cessation may have been due to a particular cause such as that to which the hon. Member refers. With regard to the second part [illegible]ion, it will not be possible under the Widows', Orphans', and Old Age Contributory Pensions Bill for a claim to benefits in respect of his own insurance to be made by a person who is out of insurance at the time of the claim.

Pollution of the River Lee.

Captain **GARRO-JONES** asked the Minister of Health how long he anticipated it would be before the measure he contemplated for improving the condition of the River Lee would take effect; whether these measures, when completed, would entirely remove the nuisance of crude sewage; and whether, in order to relieve the anxiety of those to whom this nuisance caused risk to health, he could undertake to press forward the measure with the utmost expedition.—Mr. **NEVILLE CHAMBERLAIN** replied: The two places which most affect the state of the river at Hackney are Enfield and Edmonton. The new works at the former are expected to come into operation in a few weeks. The first instalment of the new measures at the latter place should come into operation in about six months time; I am informed that the work is being pushed forward. I am advised that when these works and those at Walthamstow and Leyton come into full effect, the present state of the river should be remedied.

Deaths from Measles.

Mr. **FORREST** asked the Minister of Health the total number of cases of measles for the last half-year and the total of deaths resulting therefrom; and whether his department could express any reason for the prevalence of this malady in the British Isles.—Mr. **NEVILLE CHAMBERLAIN** replied: Measles is not generally notifiable in England and Wales and I am, therefore, unable to give the total number of cases of this disease which occurred during the last half-year. The number of deaths from measles in England and Wales during the first quarter of the present year was 1020, but this is a provisional figure and the number of deaths during the second quarter is not yet available. I am advised that no specific reason can be given for the prevalence of this disease, but that there is no evidence of exceptional incidence in the country as a whole.

Administration of Maternity Benefit.

Colonel **ENGLAND** asked the Minister of Health whether his attention had been called to the statement of the late principal medical officer of the Ministry of Health attacking the administration of the maternity benefit by the approved societies; and whether the preference expressed for its administration by local public health authorities was entertained by his present advisers.—Mr. **NEVILLE CHAMBERLAIN** replied: The statement to which I assume that my hon. friend refers was made, not by a late officer of the Ministry of Health, but by the former medical officer of the Local Government Board. The matter in question is within the purview of the Royal Commission on National Health Insurance, and I propose to await their report before expressing any opinion upon it.

High Mortality in Market Drayton.

Mr. **GRIFFITHS** asked the Minister of Health whether he had received a reply from the Shropshire county council with regard to certain suggestions arising out of the report of his inspector as to the high mortality of Market Drayton, which was communicated to that council; and, if so, whether he would now publish the report, in order to assist in a movement to save the infants in the district in question.—Mr. **NEVILLE CHAMBERLAIN** replied: The answer to the first part of the question is in the affirmative. As regards the second part, I would refer the hon. Member to the answer which I gave on July 2nd.

The Spahlinger Treatment of Tuberculosis.

Mr. **CHARLES EDWARDS** asked the Minister of Health whether he had seen the report of the medical men who were Members of this House who had been investigating the Spahlinger treatment and its effects; and whether, seeing that it was so favourable to that treatment, he would take steps to ensure that it should be made available for sufferers in this country.—Mr. **NEVILLE CHAMBERLAIN** replied: I have not yet seen this report, but I understand that the conclusion reached is that a *prima facie* case has been made out for the Spahlinger treatment, and that the report recommends that an exhaustive trial of the remedy should be made. As regards the second part of the question, I may point out that I have repeatedly stated that I am anxious to arrange for a scientif[illegible]gation of this method of treatment in this count[illegible] the materials are made available. I have bee[illegible] three years for these materials, but I am [illegible]formation as to when they are likely to be [illegible]stand that the report referred to [illegible] the treatment is or can soon [illegible]ry. Some [illegible] medical [illegible] Geneva [illegible] de[illegible] this and of con[illegible]

MONDAY, JULY 13TH.

Tubercle Bacilli in Milk.

Mr. VERNON DAVIES asked the Minister of Health if he had received a copy of the resolution passed at the eleventh annual conference of the National Association for the Prevention of Tuberculosis to the effect that a considerable proportion of tuberculosis in childhood is due to infection through the presence of tubercle bacilli in milk offered for human food, and urging His Majesty's Government to render effective the provisions of the Milk and Dairies Act; and whether he was prepared to act upon this suggestion.—Sir KINGSLEY WOOD replied: My right hon. friend has seen the resolution referred to. The Milk and Dairies Act of 1915, which deals with this subject, will be brought into operation on Sept. 1st next.

Unregistered Midwives.

Mr. BENNETT asked the Minister of Health whether representations had been made to him, and if so, by whom, in favour of the elimination of unregistered practising midwives; and whether, in that case, he could state the views of the department on the matter and the likelihood of obtaining an adequate number of registered midwives.—Mr. NEVILLE CHAMBERLAIN replied: Yes, Sir, I have received many such representations from local supervising authorities and other bodies. I am in favour of the elimination of unregistered midwives, and I do not anticipate difficulty in obtaining an adequate number of registered midwives. I have it in mind to deal with the matter in a Bill to amend the Midwives Act which I propose to introduce as soon as other commitments allow.

TUESDAY, JULY 14TH.

Midwives for Insured Persons.

Colonel DAY asked the Minister of Health whether he was prepared to provide contributions from the funds available under the National Health Insurance Act towards district nursing associations employing qualified midwives to attend insured persons, in view of the importance of these associations among health services.—Mr. NEVILLE CHAMBERLAIN replied: An approved society is entitled to devote part of its disposable surplus on valuation to making payments towards the cost of providing nursing for its members, and may also make subscriptions or donations from its benefit fund for the support of district nurses. There is not, however, any provision in the National Health Insurance Act for the making of payments for the specific purpose of securing the attendance of midwives on insured women at confinement, and before considering the desirability of amending legislation in this direction I must await the report of the Royal Commission on National Health Insurance.

Sale of Tainted Food.

Colonel DAY asked the Minister of Health whether he was aware that recently in the borough of Lambeth it was found that a local meat retailer boiled pork and beef in a portable copper situated in a yard full of flies and other insects attracted by neighbouring dustbins, and that the medical officer of health traced 24 cases of food poisoning to this tainted source; and would he consider introducing legislation to give local authorities increased power in order to deal with such practices which were dangerous to public health.—Sir KINGSLEY WOOD replied: My right hon. friend has received a copy of the report of the medical officer of health on the case to which the hon. and gallant Member refers. He is considering what steps may be practicable and desirable with a view to regulating the conditions under which food is prepared.

IRISH FREE STATE: MEDICAL MEN AS CANDIDATES FOR THE SENATE.—Our Dublin correspondent writes: The names of a few medical men are included in the panel of candidates from whom 19 vacancies in the Senate are to be filled in September. Among them are Mr. H. L. Barniville, F.R.C.S.I., an outgoing senator who seeks re-election; Sir Arthur Chance, a past President of the Royal College of Surgeons in Ireland; Mr. Denis Kennedy, F.R.C.S.I.; Mr. P. McCarten, F.R.C.S.I., formerly a member of the Dail; and Dr. Anthony McBride, of Castlebar.

NORTH PERSIAN FORCES MEMORIAL MEDAL.—Captain W. H. Dye, R.A.M.C., has been awarded this medal for the year 1924 for his paper *Schistosomiasis and Splenomegaly in Central Africa*, published in the *Journal of the R.A.M.C.* of September, 1924. At the time this work was done Captain Dye was seconded from the Royal Army Medical Corps and was doing duty under the Colonial Office in Nyasaland. This is the second award of a medal to be given annually for the best paper (reaching a certain standard) on tropical medicine or hygiene published during the preceding 12 months by any medical officer in the Services of under 12 years' seniority.

Medical News.

UNIVERSITY OF DURHAM.—At Convocations held on June 30th and July 1st the following medical degrees were conferred:—

Doctor of Medicine.—John F. C. Braine, Jabez E. Dainty, Thomas Ruddock-West, Eleanor H. Russell, Harold Williamson (*in absentia*), George Hurrell, Mona Kirkhouse and Eric H. Shaw.

Doctor of Medicine for Practitioners of 15 Years' Standing.—James Ross, Albert Turner, Henry S. Brown, and Philip T. Harper.

Bachelor of Medicine and Bachelor of Surgery.—Drummond R. F. Bertram, Frank H. Blackburn, Nora E. Coltman, Eric V. Griffiths, John T. Holliday, Marjory G. T. Jacks, Ethel G. Potts, Francis E. Stabler, Stuart C. Stonier, Reginald Wear, Charles W. Arnot, Abraham Brodie, John Brown, Alfred Charlton, John R. Carson, Austen H. Holmes, Sinclair Hughson, Hirsch Levy, James D. W. McCracken, Donald W. MacLaren, William C. Pinkney, Arthur de Redder, Walter Toward, and Charles C. Ungley.

The following received the Diploma in Public Health (D.P.H.):—

Siegfried Annecke and Harold C. Simpson.

The following received the Licence in Dental Surgery (L.D.S.):—

Thomas E. Coulson, Wilfred A. Gale, Donald Gibson, Elsie L. Peet, and Norman Wilkinson.

At the Third Examination for the degrees of Bachelor of Medicine and Bachelor of Surgery the undermentioned candidates satisfied the examiners in the following subjects:—

Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology.—Oswald C. Dobson and William Irving (with second-class honours), Ronald E. Alderson, Max Davison, Joseph Furman, William R. S. Good, David Gamsu, Rebecca Harbit, Douglas E. Hearn, William B. Hicks, Gerald Holmes, Dennis S. Jackson, Thomas F. Jarman, Maurice Levi, Cyril Mason, Gilbert McLaren, George N. Myers, Harry P. Nelson, Leslie D. Nelson, Eleanor Patterson, Hugh C. S. Pimblett, Edward Porteus, Victor B. Purvis, Cyril F. Richardson, Francis H. Robson, Gibson Salisbury, and Stanley W. Smith.

UNIVERSITY OF LIVERPOOL.—At examinations held recently the following candidates were successful in the undermentioned subjects:—

DEGREE OF M.D.

S. B. Herd, Elizabeth Hunt, G. W. Phillips, and D. Riding.

DEGREES OF M.B. AND CH.B. (HONOURS).

Class I.—*†Gwyneth Griffith and †‡G. McNichol.

Class II.—‡L. J. A. Loewenthal, ‡J. C. Ross, and *C. E. Unsworth

* Distinction in Surgery. † Distinction in Obstetrics. ‡ Distinction in Medicine.

FINAL EXAMINATION FOR DEGREES OF M.B. AND CH.B.

Part III.—C. P. Allen, A. T. Ashcroft, H. M. Boston, C. L. Copeland, N. L. Corkill, J. L. Donnelly, L. Earlam, Sybil C. Edwards, W. Emdin, M. Fisher, C. J. S. Garton, M. Goldberg, L. Gordon, J. Graham, Frances M. Greenhalgh, Dorothy M. Hanson, C. A. Harris, Beryl M. Hawthorn, J. C. Heal, F. C. S. Hinsbcock, R. E. Horsfall, S. Howard, J. E. Howie, E. Hughes, F. Hughes, F. P. Irvine, Elvy I. Johnstone, R. C. Jones, D. Katz, S. M. Katz, B. Krikler, J. E. S. Lloyd, W. J. Lloyd, T. R. E. Longton, H. McGrath, Isabel McKee, D. J. T. Magowan, K. N. Mawson, E. Miles, D. H. Mills, E. L. Murphy, Irene M. Neal, Winifred A. Nicholson, J. R. Oddy, H. Peaston, J. W. Reid, Miriam Roskin, Margaret E. Thomas, J. J. du Toit, J. Unsworth, Rosalind Vacher, B. J. van de S. de Villiers, and F. W. Yates.

Part II.—J. H. Boultbee, *J. L. Clegg, G. S. Clouston, K. McL. *Cobban, K. Edmundson, R. W. Eldridge, A. B. Follows, J. F. Galloway, Elinor M. Gelling, *E. E. Glenton, L. S. Goldman, *I. Gurland, Elizabeth M. Harding, D. G. Henry, Mary Hope-Simpson, *H. E. Hughes-Davies, E. Hulme, B. S. Jarvis, T. A. Jermy, A. N. Jones, *J. B. Logan, M. A. Lombard, D. B. Macaulay, J. C. McFarland, G. McLoughlin, S. G. Massey-Lynch, A. D. Polonsky, D. E. Pritchard, Muriel S. Roberts, A. V. Russell, N. R. Sheridan, Alfreda H. Slater, †G. D. Thompson, D. P. de Villiers, J. E. Wallace, R. G. Walmsley, †Kathleen M. Ward, A. K. Wilson, and Nora M. Wilson.

* With distinction in Public Health. † With distinction in Forensic Medicine and Toxicology.

Part I.—W. G. Brookes, K. M. Cobban, N. J. Crawford, W. A. Davies, W. E. Hargreaves, S. P. Meadows (distinction in Pathology), J. N. Parrington, Ivy H. Rowlands, N. P. Slade, E. S. Smith, and G. D. Thompson.

DEGREE OF M.H.

First (Part I.) Examination.—B. L. Davis.

DIPLOMA IN PUBLIC HEALTH.

J. G. L. Jones, Dorothy G. E. Potter, Frances Weightman, and D. A. Woodeson

UNIVERSITY OF MANCHESTER.—The Council of the University and the board of management of the Manchester Royal Infirmary have instituted a new laboratory for clinical investigations. The laboratory, which is located in the Royal Infirmary, will be placed in charge of a Director, who will have the status of a lecturer in the University. Mr. W. M. Roberts, M.Sc., M.B., Ch.B. Manch., who has been appointed as Director, at present holds the position of assistant lecturer in chemical pathology. The following appointments have been made: Lecturer in Anatomy: Mr. David Stewart. Lecturer in Applied Anatomy: Mr. R. S. Paterson. Lecturer in Systematic Medicine: Dr. T. H. Oliver. Lecturer in medicine for Dental Students: Dr. C. H. Melland. The following awards have been made: Gold Medal for M.D. Thesis: W. M. Roberts; commendation for M.D. Thesis: A. M. Jones, Donald Ramage, and J. G. Woolham. Harling Fellowship: J. West; Prof. Tom Jones Memorial Surgical Fellowship: Leslie Morris; Platt Physiological Scholarship: W. H. Newton; Tom Jones Exhibition in Anatomy: F. N. Marshall.

At examinations held recently the following candidates were successful in the subjects indicated:—

FINAL M.B. AND CH.B. EXAMINATION.

*F. H. Smirk (first-class honours), N. W. Bolton and G. H. H. Booth (second-class honours), A. R. Addey-Redfern, Solomon Bernstein, Lilian Bond, Geoffrey Coope, T. A. Danby, A. A. Davis, †N. E. Delaney, †Kathleen Dickinson, Madge E. Edwards, Mary Evans, C. R. Fielding, Miriam Florentin, E. A. Gerrard, Mary Harburn, James Haslam, †May Johnson, Walter Johnson, Barbara M. Knight, G. F. Langford, G. H. March, C. T. Marshall, E. A. Marson, Ethel Morris, William Mottershead, †S. L. Mucklow, Archer Pearson, Henry Penman, †Joan Robinson, T. W. Rothwell, M. R. Sagar, N. F. Seed, W. H. Shepley, Joseph Shlosberg, Lois Stent, Jane B. Stubbs, Samuel Whalley, K. K. Wood, P. B. Wood, Reginald Wood, N. A. J. Young.

* Distinction in Medicine. † Distinction in Forensic Medicine.

Forensic Medicine and Hygiene and Preventive Medicine.—C. H. Bamford, Frances H. Bowden, John Crook, L. F. Evans (distinction in Forensic Medicine), Agnes G. Smiley, and J. C. Wilson.

Medicine.—Frances H. Bowden.

Hygiene and Preventive Medicine.—H. H. Bullough, I. H. Freedlander, R. M. Pearce, and A. D. Shubsachs.

Obstetrics and Surgery.—Louise Aronovich, Marion L. Bainbridge, A. R. Barber, J. R. Beal, Peter Bester, R. H. Blackburn, Florence M. Blades, Agnes Bodoano, Lillie M. Burton, S. J. Firth, T. S. Hanlin, F. S. Hawkins, Barnett Hirsh, ‡R. L. Holt, John Hunt, T. J. Kay, H. B. Kilroe, W. D. Mitton, R. J. Owen, Raphael Shaffer, W. S. Slater, Graham Stenhouse, Olive de la W. Turner, and E. J. Warburton.

Obstetrics.—‡H. K. Ashworth, Zaky Hanna, and Harry Pigott.

‡ Distinction in Obstetrics.

THIRD M.B. AND CH.B. EXAMINATION.

Pathology.—R. S. Abraham, Doris Bernard, J. W. Brooks, Louie J. Burton, Margaret Egan, Arthur Hancock, Ernest Heard, G. L. Normington, I. M. Preston, Nora Ridehalgh, C. D. Roff, R. F. Sheppard, and Donald Starr.

Pharmacology.—S. K. Appleton, Dorothy Arning, Harold Arstall, A. H. Baker, Dorothy M. Bradley, H. J. Brennan, Agnes N. Buckley, M. A. Chamberlain, E. B. Davies, Ralph Edmondson, Muriel M. Edwards, Amy H. Herbert, I. M. Hughes, J. H. Jones, Morris Levine, J. A. Longworth, Jean M. Marshall, H. E. Martin, J. S. Miller, Robert Newton (with distinction), Stanley Nowell, R. P. Osborne, G. H. Racklyeft, Norah Regan, Marshall Robinon, S. L. Rowley, Eleanor H. Schill, Lucy Stokoe, Alfred Thomas, F. F. Waddy, and Josephine Walmsley.

DEGREE OF CH.M.

J. A. Panton.

DIPLOMA IN BACTERIOLOGY.

Marion H. Black and G. E. Shaw.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

W. G. Thomson and C. B. V. Walker.

UNIVERSITY OF BRISTOL.—At examinations recently held the following candidates were successful:—

FINAL EXAMINATION FOR DEGREES OF M.B., CH.B.

Part I. (including Forensic Medicine and Toxicology).—Helen M. Aldwinckle, Cecily Franco-Hayhurst, Frederic W. T. Hughes, Ernest May, Richard E. Satchwell, and Stanley P. Taylor.

Part II. (completing examination).—David H. Beatson, Harry W. Brassington, Bessie V. F. Dawkins, Charles H. Durnford, William S. Ormiston, Maurice E. J. Packer, Yolande de la Pasture, Cecil P. Porter, and Thomas W. Ware.

Group II. (completing examination).—Elizabeth E. Benson, Margaret P. Posthuma, and Kathleen M. Willmore.

Group I. (completing examination).—Charles F. R. Killick.

EXAMINATION FOR DIPLOMA IN PUBLIC HEALTH.

Part II. (completing examination).—Frederic P. Mackie and Norah A. M. Rodger.

FINAL EXAMINATION FOR DIPLOMA IN DENTAL SURGERY.

Christopher S. Cossham and Sydney Phillips.

UNIVERSITY OF LEEDS.—At the Summer Graduation ceremony on July 4th the following degrees were conferred in the Faculty of Medicine:—

M.D.—Arthur Massey and Harry A. Sinson.

Ch.M.—John T. Blackburn (with distinction).

M.B., Ch.B.—With second-class honours: David R. Allison, Albert Hemingway, Matthew Masser, James L. Moorhouse, James H. O'Donnell, Michael Rabinovich, Rosamond E. Roper, and Geoffrey W. Taylor. Ordinary degree: Maurice Backwell, Leslie V. Broadhead, Isaac Cainer, Francis R. Curtis, John Duncan, John Ewing, Wilfred S. Flowers, Glen Gorstige, John R. S. Greenwood, Philip V. Hardwick, John L. Hartley, Fannie Hirst, James C. Lamont, Sam Leviten, and Edith V. Olver.

UNIVERSITY OF ABERDEEN.—At the Graduation ceremony held on July 9th the honorary degree of Doctor of Laws (LL.D.) was conferred on Dr. John J. R. Macleod, F.R.S., Nobel Prizeman in Medicine, 1923; Professor of Physiology at the University of Toronto. The following degrees were also conferred:—

DOCTOR OF MEDICINE.

*Robert Cruickshank, *John B. Duguid, †Cecil B. Hogg, Arthur A. Hearne (in absentia), and Archibald C. Irvine (in absentia).

* Awarded highest honours for thesis. † Awarded commendation for thesis.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Douglas Archibald, Horace A. Barker, Catherine H. Baxter, Alexander Brooks, William B. B. Brown, William Bruce, Hew M. N. Calder, Hugh M. Crombie, Alexander Cruickshank, Williamina Cruickshank, Marjorie J. M. Dow, Mary M. Farquhar, William Ferguson, Samuel H. Fine, William Gavin, Henderson Gow, *Walter Graham, *Dorothy M. Harris, Douglas C. Henderson, William F. Ingram, Donald B. C. Lawson, James H. McDonald, John C. MacFarlane, George R. Mackay, John B. Mackay, George N. McLaren, Charles E. Mathieson, Graeme M. M. Menzies, William Menzies, James Murray, Alexander D. Rankin, Archibald C. Reid, Hugh L. Rettie, John M. Ritchie, Grace M. Robinson, Ephraim Sacks, Lyndesay R. D. Smith, *Williamina Stephen, *Gordon Thow, Adam N. S. Watt, Enid M. O. Will, Douglas Wilson, *Edith B. Wilson, and James Wright.

* Completed Final Examination with distinction.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics; Jurisprudence and Hygiene; Pathology and Bacteriology.—Edmund P. N. M. Early (passed on high marks), Shirley D. K. Roberts, Menzies L. M'Cauley, Gerald S. Smyth, Robert S. F. Hennessey, Albert Sachs, Robert A. J. Holmes-Ievers, Martinus G. J. Booysen, George S. Gardner, Edward W. Bingham, Arthur N. B. Odbert, John O. Bennett, Norman J. U. Mather, John H. Stephens, Christiaan de W. Meintjes, Daniel A. O'C. Quinlan, Herbert Nelson, Hubert C. Weir, John C. Collins, and John B. Patrick.

Part II., Medicine (M.B.).—James E. M'Cauley, Roy K. Carson, Gladys M. A. Lowry, James W. Wallace, Alexander D. M'Lean, Hope Trant, James J. Cusack, Edward C. Dudgeon, Harry Waters, William H. Coen, Joseph V. Pincus, Kathleen M. Ball, Johan N. S. Gouws, Carol R. J. Boland, Harris Tomkin, George R. L. Jordan, John E. Stokes, Edwin S. A. Crawford, John St. Clair, Philip B. Robinson, Charles L. Taylor, David N. Power, Norah M. Smith, Gerard A. A. Powell, and William O. Warrington.

Surgery (B.Ch.).—Charles F. D. M'Caldin, O'Donel T. D. Browne, Joseph R. Gregory, William C. Somerville-Large, Thomas C. Foster, Robert L. Forsyth, Thomas W. MacDowell, Oliver Chance, James W. Wallace, Ralph A. Webner, William Gallaugher, James Dick, John F. Wilde, William P. E. M'Intyre, Hope Trant, Mary Galvin, Augusta M. Young, Mary C. Livingston, Launcelot W. R. Haskins, Kathleen D. Murison, Agnes L. Kelly, Noel G. M'Auliffe, Norman M. Greeves, Harry Waters, Annie T. Deane, and Gideon J. Joubert.

Midwifery (B.A.O.).—Seymour F. Heatley, Richard G. Keays, Ransome M. Allardyce, and John H. M'Lean (passed on high marks), William B. Roantree, Edward M'Alpine, James W. Bowden, Jack M. Selkon, Nancie N. Lowther, Robert Kahn, William Russell, Stella C. Ross, Jane D. Fulton, Henry J. Roche, William Magowan, Daniel J. Roux, Frances E. O'Connor, Philip F. Palmer, Gladys L. Craig, George A. Walmsley, George R. L. Jordan, Aileen Fair, and Rachel E. Porter.

DIPLOMA IN PUBLIC HEALTH.

Part I., Chemistry, Bacteriology, Physics, and Meteorology.—William F. Shell.

FINAL DENTAL EXAMINATION (B.DENT.SC.).

Dental Surgery and Pathology; Dental Mechanics and Metallurgy; Orthodontics.—Thomas M. Joyce.

Honorary Degrees.—On June 26th the honorary degree of Master in Surgery was conferred on Drs. George W. Crile and Charles H. Mayo, the public orator, Sir Robert Tate, presented the candidates to the University.—The degree of Doctor in Science was conferred on Prof. James P. Hill, F.R.S., and Sir Frederick G. Hopkins.

UNIVERSITY OF LONDON.—In the Faculty of Science the Senate awarded on June 24th the degree of Ph.D. to Annie D. Hoffert, a student of the Lister Institute of Preventive Medicine.

UNIVERSITY OF GLASGOW.—At the graduation ceremony on July 3rd Dr. Archibald J. Cronin received the degree of M.D. with high commendation.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—There will be a late afternoon course in the diagnosis and treatment of the more common diseases of the nervous system. The course will take place in the out-patient department (73, Welbeck-street) of the West End Hospital, and the lectures and demonstrations will be illustrated by cases. There will be a vacation course at the Prince of Wales's General Hospital (N.E. London Post-Graduate College, Tottenham N.) from August 3rd to 15th. During the two weeks, a ticket for either of which may be taken separately, there will be morning and afternoon sessions from 10.30 A.M. to 5.30 P.M. Each day will include clinical demonstrations, clinics, and clinical lectures, and the whole of the hospital practice will be available for study. The Queen Mary's Hospital, Stratford, will also give an intensive course on similar lines to that at the Prince of Wales's Hospital, from August 24th to Sept. 5th. Special facilities will be given at the latter hospital for the study of gynæcology and obstetrics. Throughout the month a special course will be given at the All Saints' Hospital for Urology. There will be clinical demonstrations daily and a special lecture every Wednesday dealing with the various phases of the disease. Copies of each of the above-mentioned syllabuses, as also the general programme of work, may be obtained from the Secretary, 1, Wimpole-street, W.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council of the College, held on July 9th, Sir John Bland-Sutton in the chair, Mr. James Sherren and Sir John Lynn-Thomas, having been duly re-elected and having made the declaration prescribed by the Charter of 1800, took their seats as members of the Council. Mr. Arthur Burgess having been elected and having made the declaration took his seat as member of Council. Mr. Graham S. Simpson having been introduced and made the necessary declaration was admitted a member of the Court of Examiners. Mr. Cecil F. Beadles was appointed Pathological Curator of the Museum for the ensuing year. Mr. R. H. Burne was re-elected Physiological Curator and Sir Frank Colyer was re-elected Curator of the Odontological Collection. Sir John Bland-Sutton was re-elected President of the College. Mr. Walter G. Spencer was re-elected Vice-President, and Mr. James Sherren was elected Vice-President for the ensuing year. The diploma of Fellow was conferred upon Harry Roy Pomroy, Adelaide University and London Hospital, and the diploma of Member upon Edith Grace Peacock, Charing Cross Hospital.

Licences to practise dentistry were conferred upon 57 candidates who have passed the requisite examinations and have complied with the by-laws. The following are the names and schools of the successful candidates:—

F. M. Ackroyd, Guy's; H. S. Alexander and M. N. Anklesaria, Royal Dental; L. Barclay, Guy's; Marjorie K. M. Barnes, Univ. Coll.; W. L. Benson, H. F. Boosey, T. Brimmer, and G. L. N. Burden, Guy's; E. H. Butler, Royal Dental; S. Casper, Guy's; A. H. Chidley, Birmingham; T. O'R. Clancy and E. B. Corry, Guy's; H. A. Crooke, Royal Dental; W. Eddings, Univ. Coll.; C. H. Elphick, Royal Dental; A. C. Evans and G. Evans, Guy's; A. E. Foley and L. Foster, Royal Dental; G. E. Graham, Guy's; Annie H. Halperin, Univ. Coll.; N. Harris, Guy's; Katia Hranova, Royal Dental; O. S. Israilstam, Middlesex; W. R. Jenkins, Guy's; S. M. Jones, London; G. J. T. José and D. Kelvin-Davies, Guy's; C. H. B. Laughton, Royal Dental; Nesta G. Lewis, Univ. Coll.; G. B. Longhurst and A. S. Lowe, Guy's; E. C. Loxton and D. W. MacBean, Royal Dental; A. E. MacLagan, Guy's; J. G. Macvie, Manchester; R. H. Mallett, Durham; C. Malthouse, Manchester; B. S. Mead, Guy's; B. A. Morrisroe, Royal Dental; J. Partridge, Bristol; V. G. Podley, London; H. R. Peek, Birmingham; J. M. Foot, Liverpool; T. G. Phillips, Royal Dental; H. H. Revill, Guy's; T. I. Richards, Birmingham; M. Smalka, H. E. Slade, E. M. Smith, and R. Thorburn, Royal Dental; D. M. Timpson and C. M. Veysey, Guy's; and H. K. Wallace and A. A. Wilkinson, London.

The undermentioned diplomas were conferred (jointly with the Royal College of Physicians of London):—

Diploma in Psychological Medicine.—G. T. Baker, G. L. Cutts, H. T. Jones, J. J. Laws, J. B. S. Lewis, H. C. McManus, A. H. Pearce, G. F. Peters, R. G. Riches, G. R. A. de M. Rudolf, and J. Russell.

Diploma in Laryngology and Otology.—S. N. Chau, E. D. D. Dickson, R. McM. Glynn, H. E. Jowett, J. P. Kies, N. W. MacKeith, and J. H. Shaw.

THE Dickinson Travelling Research Scholarship in Medicine has been awarded by the trustees of the Manchester Royal Infirmary to Raymond Williamson, M.D. Manch., and Leslie J. Witts, M.B., Ch.B. Manch.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 24 cases were considered and £380 10s. voted to 23 applicants. The following is a summary of the new cases relieved:—

M.D. Edin., 1890, aged 71, practised in S. Africa and held several travelling appointments. Applicant asks for a grant to enable him to get massage. He is bedridden and also has chronic bronchitis. Two brothers meet the nursing home fees of 4 guineas a week, but cannot do any more for him. Voted £5.

Daughter, aged 48, of L.R.C.P. Edin. who practised in Wales and died in 1924. Applicant is not mentally able to support herself, and her only income from investments amounts to £48 per annum. A brother in Canada gave £20. Rent is £31 per annum. Voted £15 in 12 monthly instalments.

Daughter, aged 58, of M.R.C.S., 1843, who practised in Warwickshire and died in 1877. Applicant lost most of her money by lending large sums to so-called friends who did not repay. She is now left with capital which brings in 15s. a week, but she has had to draw upon this capital at the rate of 32s. 6d. a week to meet expenses. She lives with an adopted sister. A cousin gave the applicant £6 last year. Rent and rates amount to £24 per annum. Voted £18 in 12 instalments and referred to our Guild for clothing.

Subscriptions may be sent to the honorary treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, W. 1.

MENTAL HOSPITALS ASSOCIATION.—The seventh annual meeting of this Association was held on July 8th, when the report of the Executive Committee was received. The committee gave evidence before the Royal Commission on Lunacy Reform, and continues to take every opportunity of urging on the Government the necessity for so altering the existing system as to bring it into line with modern ideas on treatment of mental disorder. Representatives have met members of the National Asylum Workers Union to discuss hours of duty and rates of pay, and recommendations were agreed to with a view to removing certain anomalies. There have also been conferences with the Medico-Psychological Association, the Association of Clerks and Stewards of Mental Hospitals, and the National Union to discuss proposed amendments of the Asylum Officers Superannuation Act, 1909. The committee was unable to advise support of the draft Bill until more definite actuarial investigations had been made. The meeting then discussed the question of adopting a flat rate of sick-pay in all districts for prolonged periods of illness. A motion instructing the Executive Committee to take steps to secure the flat rate was carried. It was also proposed that steps be taken to secure a larger contribution from Imperial funds for local maintenance of mental cases.

ROYAL SOCIETY OF MEDICINE: ELECTION OF OFFICERS.—At the annual general meeting, held on July 1st, the following officers were elected for the session 1925-26:—

President: Sir StClair Thomson. Past President: Sir William Hale-White. Hon. Treasurers: C. H. Fagge, M.S., and E. Farquhar Buzzard, M.D. Hon. Librarians: Walter G. Spencer, M.S., and W. Bulloch, M.D., F.R.S. Hon. Secretaries: W. Girling Ball, F.R.C.S., and H. Letheby Tidy, M.D. Other Members of Council: Sir James Berry, F.R.C.S.; Sir George Blacker, M.D.; Sir Charlton Briscoe, M.D.; Sir George Buchanan, M.D.; H. W. Carson, F.R.C.S.; Maurice A. Cassidy, M.D.; V. Zachary Cope, M.S.; T. Watts Eden, M.D.; R. C. Elmslie, M.S.; A. M. H. Gray, M.D.; Robert Hutchison, M.D.; Cyril A. R. Nitch, M.S.; Herbert J. Paterson, M.C.; Herbert Tilley, F.R.C.S.; G. de Bec Turtle, M.D.; A. E. Webb-Johnson, F.R.C.S.; and E. F. White, F.R.C.S.

The Presidents of the Sections are ex-officio Vice-Presidents of the Society and Members of the Council. The following have been elected:—

Anæsthetics: F. E. Shipway, M.D. Balneology and Climatology: R. Llewellyn Jones Llewellyn, M.B. Study of Disease in Children: Philip Turner, M.S. Clinical: G. Newton Pitt, M.D. Comparative Medicine: Frederick T. G. Hobday, F.R.C.V.S. Dermatology: J. H. Sequeira, M.D. Electro-Therapeutics: Alastair MacGregor, M.D. Epidemiology and State Medicine: J. C. McVail, M.D. History of Medicine: J. D. Rolleston, M.D. Laryngology: W. H. Kelson, M.D. Medicine: Hugh Thursfield, M.D. Neurology: H. Campbell Thomson, M.D. Obstetrics and Gynæcology: T. G. Stevens, F.R.C.S. Odontology: J. Lewin Payne. Ophthalmology: Sir Arnold Lawson, F.R.C.S. Orthopædics: A. S. Blundell Bankart, M.Ch. Otology: G. J. Jenkins, F.R.C.S. Pathology: J. A. Murray, M.D., F.R.S. Psychiatry: R. H. Cole, M.D. Surgery: Sir Lenthal Cheatle, F.R.C.S. Therapeutics and Pharmacology: George Graham, M.D. Tropical Diseases and Parasitology: Sir William Prout, M.B. Urology: R. H. Jocelyn Swan, M.S. War: Sir William Leishman, M.B., F.R.S.

The new Council takes up office on Oct. 1st.

A Guy's Hospital "Record."—Last year Guy's dealt with 10,017 in-patients—the largest number ever recorded. Their average stay was 21¼ days. There were 124,000 out-patients, of whom only 179 were unable to pay for their medicines.

Hospital Needs of South Wales.—At a recent meeting of the Cardiff Medical Society it was stated that although the population of the Cardiff end of Glamorganshire numbers 800,000, only 850 hospital beds are available. On the basis of 2 beds per 1000 people, 1600 beds are needed.

The Plymouth Hospitals.—The exhibition opened at Plymouth by Prince Henry, reinforced by a fête and fair, on behalf of the Plymouth hospitals, has been successful beyond expectation. It was hoped to raise £10,000; more than £20,000 was actually obtained.

An Institute of Otology.—The Right Hon. T. R. Ferens, of Hull, has given £20,000 to the Medical School of Middlesex Hospital for the foundation of an Institute of Otology. It is intended to establish a laboratory, museum, and library entirely devoted to research in diseases of the ear, nose, and throat, and it is hoped that it may eventually be possible to create studentships.

A Miners' Rest Home.—At Rudyard Lake, about 12 miles from Stoke-on-Trent,.a rest home for the miners of North Staffordshire was opened on July 4th. The site for the home, the building, and its equipment cost £61,000, raised by the 1*d.* a ton levy for the Miners' Welfare Fund. It contains 42 beds for miners recovering from accident or illness, with billiard and other recreation rooms, and facilities are provided for outdoor amusements and exercise.

New Sanatorium for Oldham.—At a cost of £10,000 the Oldham Health Committee have built a new sanatorium at Strinesdale, to replace the wooden hospital erected about 30 years ago. Situated on an eminence adjoining the Yorkshire moors, about 1050 feet above sea-level, the new building is so constructed as to get the sunlight and to protect the patients as much as possible from the wind. The building provides accommodation on two floors for 48 patients, 24 in the three end wards, and the remainder in separate cubicles. The official opening took place on June 29th.

Carter Hospital, Middlesbrough. — Nearly 20 years ago the late Alderman Carter, of Middlesbrough, bequeathed £40,000 for the provision of a hospital. This sum has accumulated to about £100,000, and the Alderman Carter Bequest Hospital is now approaching completion. By restricting the number of beds to 52 a complete endowment will be provided. Eight of the beds are for patients whose payments will just clear the cost of maintenance. The hospital, which covers four acres, is divided into three two-storey blocks and is being supplied with the most modern equipment and appliances.

Society of M.O.H.'s: Complimentary Dinner to Sir John Robertson.—A complimentary dinner to Sir John and Lady Robertson was given by the Midland branch of the Society of Medical Officers of Health at the Queen's Hotel, Birmingham, on July 10th. The President of the branch, Dr. R. Woolsey Stocks, was in the chair. Dr. G. F. Buchan, in proposing the toast of the evening, referred to Dr. Robertson's passion for research in every branch of public health which had been the mainspring of his life, and had rendered his judgment sound on housing and the food-supply, and in the foundation of the first municipal sanatorium at Cheltenham. In cancer research his work had been silent and steadfast. His willingness to befriend all with whom he came in contact was reaffirmed by Miss Bartlett, chairman of the Birmingham Health Committee. Sir John Robertson, in reply, described the honour as a recognition of the merit of the public health service. Public health work was, he said, happy work, though results were not accomplished rapidly. Reduction of mortality in towns to nearly one-half, and infant mortality to less than half, was no doubt due to a number of causes, but medical officers of health had at all events set the pace by educational effort. The war had put back the clock 30 years for public health, but the town-planning legislation recently passed was of first-rate importance. A country breeding, and a taste for agriculture and geology he had ound of great value in his work at St. Helens, Sheffield, and years at Birmingham. Mr. Furneaux Jordan proposed, . R. A. Lyster responded, to the toast of the Society .H.'s. A well-chosen musical programme added to tivity of the evening.

The Census Report.—The final volume presenting tabulated statistics derived from the 1921 Census of England and Wales is now published (H.M. Stationery Office. 13*s.*). It contains 200 folio pages of closely printed figures, and presents for the country as a whole, and for certain subdivisions of it also, statistics of the same nature as those published in the earlier volumes for each country. It also includes certain hitherto unpublished figures dealing with populations of county court circuits and districts, seamen and fishermen not enumerated on Census night, and persons under service discipline outside Great Britain.

Guy's Hospital Medical School.—The following scholarships have been awarded: Entrance Scholarship in Arts, £100, Herbert Aidan Constable, Wimbledon College; Entrance Scholarship in Science, £100, divided between Walter Horace Allen, Guy's Hospital Medical School, and Frederick Harwood Stevenson, St. Paul's School; Confined Scholarship in Science, £100, William John Ferguson, Crampton County School and Guy's Hospital Medical School. Guy's Hospital Dental School: War Memorial Scholarship in Arts, £40 for four years, Joseph Cuthbert McNeill, Wadham College, Oxford; Entrance Scholarship in Science, £40 for four years, Geoffrey Blake Palmer, Emanuel School.

Medical Tour to the Spas of Italy.—A second study tour for medical men to the spas and climatic health resorts of Italy, organised by the Italian State Tourist Department, will leave Milan on Sept. 5th, visiting among other places, San Pellegrino, Fonte Bracca, Acqui, Leghorn, Montecatini, Monsummano, Chianciano, Fiuggi, Alassio, and Viareggio, the tour ending at Rome on Sept. 21st. The journey is under the guidance of Prof. Guido Ruata, M.D., and medical men speaking English, French, Italian, and German will act as interpreters. The party is limited to 200 and the charge for the complete tour is 1600 lire. This includes first-class accommodation. There are still a few vacancies. Further particulars can be obtained from the Italian State Railways Tourist Office, 12, Waterloo-place, Regent-street, S.W. 1.

Donations and Bequests.—Mrs. Emily Louisa Acret, Rosslyn Hill, Hampstead, bequeathed £2000 to Mabel Acret, of Ontario, lately a nursing sister of Queen Alexandra's Nursing Sisters Reserve "in recognition of her services to the Old Country in the Great War," and £2000 to the Hampstead General Hospital for the endowment of an "Acret Bed"; £200 to the Soldiers' Daughters' Home, N.W.; £100 to the Royal Sailors' Daughters' Home, N.W.; and her freehold property at Belvedere, Kent, to the Blind School, Swiss Cottage, for an "Acret" annuity.—A gift of £1000 has been made by the Mercers' Company to the Fulham, Chelsea, and Kensington General Hospital for building funds.—Mr. George Henderson, an East India merchant, of Palace Court, W., left £1000 to the London Hospital.—Mr. John Alexander Kennedy, draper, of Sunderland, left £500 each to the Sunderland Royal Infirmary, the Children's Hospital associated with the Royal Infirmary, £100 each to the Heatherdene Home, Harrogate, the Sunderland Orphan Asylum, the Northern Counties Orphan Institution for Boys, Newcastle-upon-Tyne, and £50 to the Royal Institution for the Blind, Newcastle. On the decease of his wife he left £1000 each to the Sutherland Royal Infirmary for a Jean Ross Kennedy bed and to the Children's Hospital in connexion with the Royal Infirmary for a similar bed.—The late Mrs. Harriett Sturges, of Birmingham, who left property of the value of over £30,000, bequeathed the residue after certain small bequests equally between the Birmingham General Hospital; the Queen's Hospital, Birmingham; the Birmingham Children's Hospital; the Birmingham and Midland Hospital for Women; the Birmingham Deaf and Dumb Institution; the Royal Institution for the Blind, Birmingham; and Dr. Barnardo's Homes.—The late Mr. James Taylor, M.R.C.S., of Alma-road, Clifton, Bristol, who left estate of the gross value of £22,002, among other bequests gave to Bristol University for the Medical Library all his medical books; £1000 to Epsom College for the endowment of a scholarship in memory of the Rev. W. A. Thomas, to be known as the "Thomas Scholarship"; £1000 in trust for Elizabeth Arabella Taylor for life and then to the Bristol Royal Infirmary.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, July 21st.

GENERAL MEETING OF FELLOWS: at 5.30 P.M. Ballot for election to the Fellowship.

BIOCHEMICAL SOCIETY.

SATURDAY, July 18th.—5 P.M., Joint Meeting with the Agricultural Education Association at University College, Reading).

Communications: R. H. A. Plimmer: The Action of Nitrous Acid upon Amides and some Amino Compounds. W. J. N. Burch: Some Esters of Phosphoric Acid. — Mattick and — Wright: The Influence of Administration of Certain Salts on the Inorganic Constituents of Milk. E. Ponder and W. W. Taylor: The Conductivity of Cell-suspensions. G. D. Thacker and J. R. Marrack: The State of Calcium in Body Fluids.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 20th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Donald Armour: Operations. 2 P.M., Mr. Bishop Harman: Eye Dept.

TUESDAY.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Addison: Operations.

WEDNESDAY.—2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Mr. Tyrrell Gray: Operations.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—10.30 A.M., Dr. Dowling: Skin Dept. 11 A.M., Dr. McDougal: Electrical Dept. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations of the Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. THURSDAY, July 23rd.—4 P.M., Dr. Nabarro: The Cerebro-Spinal Fluid in Health and Disease.

Appointments.

Royal Northern Hospital, Holloway: CALVERT, EDWIN G. B., M.D., M.R.C.P., Physician with charge of Out-patients; LANE-ROBERTS, C. S., F.R.C.S., Obstetric Surgeon with charge of Out-patients.

University of Manchester: STEWART, D., M.R.C.S., L.R.C.P. Lond., Lecturer in Anatomy; PATERSON, R. S., M.B., Ch.B. Manch., Lecturer in Applied Anatomy; OLIVER, T. H., M.D. Manch., Lecturer in Systematic Medicine; MELLAND, C. H., M.D. Lond., B.Sc. Manch., Lecturer in Medicine for Dental Students; KELLY, A. C., M.B., Ch.B. Manch., Demonstrator in Anatomy.

Vacancies.

For further information refer to the advertisement columns.

Aylesbury, Royal Buckinghamshire Hospital.—Res. M.O. £150.

Barbados General Hospital.—Sen. Res. Surg. £330. Jun. Res. Surg. £300.

Bath, Royal Mineral Water Hospital.—Res. M.O. £130.

Birkenhead Union Infirmary.—Res. Asst. M.O. £300.

Birmingham Cripples' Union and Royal Orthopædic and Spinal Hospital.—Jun. H.S. £150.

Birmingham, Queen's Hospital.—Asst. Obstet. O. £50.

Birmingham University.—Lecturer in Physiological Dept. £300. Demonstrator of Anatomy. £300. Also Walter Myers Travelling Studentship. £300.

Cairo, School of Dental Surgery.—Supt. and Lecturer in Metallurgy, &c. £E.600. Lecturer in Surg. £E.480. Asst. Lecturer in Surgery. £E.360. Lecturer in Mechanics. £E.480.

Cardiff City Mental Hospital, Whitchurch.—Res. Clin. Asst. 30 guineas.

Cumberland and Westmorland Mental Hospital, Jun. Asst. M.O. £350.

Deptford Metropolitan Borough.—Asst. M.O.H. and Tuberc. O. £750.

Durham County Mental Hospital.—Asst. M.O. £400.

Eastbourne, Royal Eye Hospital.—Hon. Ophth. S.

East London, South Africa Frere Hospital.—Res. M.O. £300.

Evelina Hospital for Children, Southwark, S.E.—H.S. £120.

Gloucestershire Royal Infirmary, &c., Gloucester.—Asst. H.S. £150.

Grosvenor Hospital for Women, Vincent-square.—Anæsth.

Hampstead General and N.W. London Hospital, Haverstock-hill, N.W.—Radiologist. £100.

Hertford County Hospital.—H.S. £150.

Hong Kong University.—Reader in Biology. £600.

Liverpool University.—Professor of Entomology. £800.

Manchester, Ancoats Hospital.—Asst. H.P. £100. Also Anæsth. 10s. 6d. per attendance.

Margate, Royal Sea Bathing Hospital.—H.S. £200.

Northampton General Hospital.—Hon. Asst. S.

Pietermaritzburg, Grey's Hospital.—Male H.S. £500.

Queen's Hospital for Children.—Asst. Cas. M.O. £100.

St. Mark's Hospital for Cancer, &c., City-road, E.C.—Hon. S. Also Hon. Asst. S.

St. Mary's Hospital for Women and Children, Plaistow.—Clin. Asst.

St. Marylebone General Dispensary.—Gynæcologist.

St. Paul's Hospital for Skin, &c., Diseases.—Hon. Anæsth.

Samaritan Free Hospital for Women.—H.S. £100.

Southampton, Royal South Hants Hospital.—Jun. H.S. £150.

Whittingham, Preston, County Mental Hospital.—Temp. M.O. £7 per week.

Willesden General Hospital.—Hon. Anæsth.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments for Certifying Factory Surgeons: Snaith, Yorks; and Hoddesdon, Hertford.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Districts of the Camelford, Holsworthy, and Launceston, &c., County Courts. Applications should reach the Private Secretary, Home Office, not later than August 5th.

Births, Marriages, and Deaths.

BIRTHS.

BATTERHAM.—On July 5th, at the Military Families Hospital, Cologne, the wife of Captain D. J. Batterham, R.A.M.C., of *a son.*

CLOUSTON.—On July 6th, at Lavenham, Suffolk, Olive Gwendolen *Clouston, M.R.C.S., L.R.C.P., wife of Eric C. T.* Clouston, M.R.C.S., L.R.C.P., of a son.

KERRIGAN.—On July 2nd, at Devonport, the wife of Surgeon-Lieut.-Commander C. J. M. Kerrigan, R.N., H.M. Dockyard, of a son and daughter.

RIVETT.—On July 12th, at a nursing home, to Mary, wife of Louis Carnac Rivett, of 118, Harley-street and 3, *Hanover*-terrace—a daughter.

SOUPER.—On July 11th, at Victoria-street, Aberdeen, the wife of Dr. H. Ross Souper, of a daughter.

MARRIAGES.

CLAXTON—ERVINE.—On June 30th, at Saint Saviour's Church, Denmark Hill, Dr. E. Claxton, of Bath, to Muriel Ervine, of Denmark Hill.

COLWILL—WORRINGHAM.—On July 11th, at St. Mary Abbot's, Kensington, W., Charles Kingsley Colwill, M.R.C.S., L.R.C.P., to Muriel, daughter of Mr. and Mrs. *Charles* Worringham, of Inverna-gardens, Kensington, W.

DEATHS.

CAMPBELL.—On July 3rd, at a nursing home, after an operation, George Maclean Campbell, M.C., M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., late Captain, R.A.M.C., aged 37.

CLIFFORD.—On July 8th, at his residence, 15, St. John-street, Manchester, Harold Clifford, M.B., F.R.C.S. Edin., Hon. Gynæcological Surgeon to St. Mary's Hospitals, Manchester, and the Salford Royal Hospital.

GUBBINS.—On July 8th, at Westgate, from the effects of a cycling accident, Lieut.-General Sir Launcelotte Gubbins, K.C.B., M.V.O., J.P., late Director-General A.M.S., in his 76th year.

REW.—On July 6th, died suddenly, G. R. Rew, M.R.C.S., L.R.C.P., of Bedfont, Feltham, late of King's College, London.

STEWART.—On June 26th, at Stonebridge Park, William James Johnstone Stewart, M.D. Edin., D.P.H. Camb., for 22 years Medical Superintendent of the Willesden Municipal Hospital, aged 57.

WICKHAM.—On June 30th, at Lenworth, Southbourne-on-Sea, Hants, Charles A. Wickham, M.R.C.S., L.R.C.P., late of Willesborough, Ashford, Kent.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

COLONIAL HEALTH REPORTS.

CAYMAN ISLANDS (DEPENDENCY OF JAMAICA).

Mr. H. H. Hutchings (Commissioner) has forwarded to the Colonial Office a report for 1923 on these three small islands in the Caribbean Sea, lying north-west of Jamaica, and approximately mid-way between that island and the south-west coast of Cuba. He states that the general health of the Dependency is good. Digestive disorders of a mild nature are prevalent, induced by the sameness of a diet of starchy foods. There is an occasional case of typhoid. Care with respect to arrivals from Jamaica have prevented the introduction of alastrim. There were 179 births in 1923 (34 per 1000) and 55 deaths (10 per 1000). The population is estimated at approximately 5253. The rainfall amounted to 54·76 inches in the Georgetown or western district of the Grand Cayman. The air temperature ranges between 70° and 80° F. in the cooler winter months, and 10° higher in summer. The nightly calms and the excessive dampness accentuate the heat of summer.

LEEWARD ISLANDS.

In the report for 1923-24 the following particulars are given respecting the five Presidencies constituting the Federation or Colony. In Antigua the estimated population on Dec. 31st, 1923, was 29,420. The births during the year were equal to a birth-rate of 38·68 per 1000, of which 78·03 were illegitimate. The death-rate was 27·56 per 1000. In the Presidency of St. Kitts-Nevis, the birth-rate was 41·7 per 1000 in St. Kitts, 30·8 in Nevis, and 28·6 in Anguilla. In Dominica the population was estimated at 38,632, the birth-rate 37·22 per 1000, and the death-rate 26·66. Illegitimate births exceeded the legitimate by 202. Montserrat had a population of 11,890. The legitimate births were 110 and the illegitimate 315, the percentages being 25·8 and 74·1 respectively. The death-rate was 15·5 per 1000. The general health of the colony during the year was satisfactory. No epidemic disease occurred. The appearance of small-pox in Antigua led to the introduction, for a period of five months, of compulsory revaccination in St. Kitts-Nevis. The campaign met with ready acceptance on the part of the public. The revaccinations performed, added to the number of those persons immunised by recent revaccination or primary vaccination, may be regarded as having effected for the present the satisfactory protection of the whole Presidency. The vigilance and precautions of the Quarantine Board and Harbour Authorities, however, have been in no way relaxed. The campaign against yaws and syphilis, which had been in abeyance for a time, was recommenced on improved lines in November, 1923. The moogrol treatment of the inmates of the Leper Asylum was continued and extended during the year with gratifying results. The epidemic of alastrim, which had been present in the island since July, 1922, and which had done considerable harm to trade owing to the quarantine restrictions imposed by other places, came to an end in September, 1923. No further cases have occurred.

MAURITIUS.

The report for 1923 is signed by Mr. H. Lalonette, Acting Assistant Colonial Secretary. The section relating to vital statistics and public health states that the estimated popu- lation on Dec. 31st was 381,678, an increase of 5193 on the last census figures. The birth-rate in the general population was 40·9 and in the Indian population 34·9 per mille, whilst the death-rates per 1000 in the two populations were 29·0 and 28·1. The mortality was remarkably low, the death-rate being the lowest since 1891. The number of deaths due to malaria and malaria cachexia (the highest death-producing factors in Mauritius) was 1979, as against 3526 the year before. The next high causes of death were pneumonia and broncho-pneumonia (1393) and diseases of early infancy (1026). There were 139 cases of plague during the year, of which 118 were fatal; the largest number of cases was, as usual, in Port Louis (117). There were 150 cases of enteric fever, as against 224 in the previous year. The infantile mortality (deaths of children under one year) gave a ratio of 139·4 per 1000 live births, as against 147·9 in 1922. There were 1557 still-births registered during the year, corresponding to a rate of 112·2 per 1000 live births. The number of cases treated in the public hospitals and at the dispensaries was 82,326, this total being much below that for 1922 and for the five-year period 1919-23. The total number of persons certified insane on Dec. 31st was 798, or 34 less than the year before. Admissions to the lunatic asylum numbered 194. At the Leper Asylum there were 37 patients (males 25, females 12) at the beginning of the year. Admissions during the year numbered 19, deaths 2, and discharges 14. The construction of the new leper asylum has been completed, and the transfer of the lepers effected. The law relative to compulsory segregation of lepers will be brought into operation at an early date. The climate is tropical, but, owing to the high elevation of the central plateau, a large part of the island enjoys a temperate and even bracing climate. The average temperature of this highland region is about 69° F., and the maximum about 80°. The low-lying coastal region has naturally a higher average temperature ranging from 90° to 70°. Mauritius lies in the track of cyclones, which are liable to occur during the months of December to April. There has been no very severe cyclone since 1892. The rainfall is irregular, and varies according to the locality and elevation. In the central portion of the island an average yearly rainfall of 175 inches is recorded. That of the coastal districts varies between 25 and 80 inches.

SEYCHELLES.

Brigadier-General Sir Joseph A. Byrne, K.B.E., C.B., the Governor of this colony, in his report for 1923, states that the population is estimated at 25,700, being an increase of 1177 since the Census of 1921. The births in 1923 numbered 771, corresponding to a rate of 30·02 per 1000. The deaths were 297, or 11·79 per 1000. This low death-rate constitutes a record, and is partly due to the fact that no epidemics of an infectious or contagious disease occurred during the year. Although almost on the equator, the climate of Seychelles is quite healthy, and owing to the absence of the anopheline mosquito malaria does not occur. The maximum shade temperature rarely exceeds 86° F., but even at night the temperature seldom falls below 74°. The hottest weather occurs during the months of March and April. The rainfall averages about 90 inches, although in some years it has reached 115 inches. The estimated total number of square miles comprised in the Seychelles Islands and their dependencies is 156¼.

TONGAN ISLANDS PROTECTORATE.

Mr. J. McOwan, the British Agent and Consul at Tonga, writes in a report for 1923-24 that the estimated population on Dec. 31st was 24,973. The birth-rate for the year was 33·21 per 1000, and the death-rate 22·98. The population includes 571 Europeans and 235 half-castes. The islands are situated 390 miles to the E.S.E. of Fiji, and have an area of 385 square miles. Queen Salote Tubou, the present queen, succeeded to the throne on the death of her father, King George Tubou II., in 1918. A Protectorate was proclaimed over the kingdom of Tonga in 1900, under which Great Britain assumed the exercise of civil and criminal jurisdiction over all subjects and foreign powers in Tonga, and an agent and consul was appointed to advise the Queen and Government, and to supervise the financial administration. The seat of government is at Nukualofa, on the island of Tongatabu. Although the Tongan group lies between latitudes 16 and 22 degrees south, and is therefore within the tropics, the climate is probably the best of any of the islands in the Western Pacific. For eight months of the year (May to November inclusive) the thermometer rarely registers higher than 83° F., and as the humidity is comparatively low during these months, Europeans do not feel the heat to the same extent as in the groups to the north. During the wet season (December to March inclusive) the temperature ranges from 65° to 94°, with a higher humidity. Malaria and tropical fevers are unknown.

THE WHISPER AS A MEASURE OF DEAFNESS.

A WHISPER, uttered at the end of expiration, is more likely than the normal voice to have a similar loudness from day to day, and that is why a whisper is used for the assessment of deafness in the French Army, no recruit who cannot hear a whisper at 18 inches being accepted for the ranks, though he may be accepted for the auxiliary services if he can hear it at anything over 9 inches. Méd. Maj. P. E. H. F. Bertein, from whose paper on "The Measurement of Deafness," in the *Archives de Médecine Militaires* for April we quote, adds that the figures 1, 3, 9 are more easily heard by men with nerve deafness; 5, 6, 8 by those with middle-ear disease. Before men are sent to the ear specialist, with whom in every doubtful case lies the ultimate decision, each should have his deafness estimated quantitatively, and more than once, by his regimental officer, to allow the honesty of the patient to be appreciated, and also possible variations in his deafness.

An Address

ON THE

EVOLUTION OF A HEALTH RESORT.

Being the Presidential Address delivered at the Annual Meeting of the British Medical Association in Bath on July 21st, 1925,

BY F. G. THOMSON, M.A. CAMB., M.D.,
M.R.C.P. LOND.,

PHYSICIAN, ROYAL UNITED HOSPITAL, BATH; CONSULTING PHYSICIAN, MINERAL WATER HOSPITAL, BATH.

THE history of a town that has been closely associated with the treatment of disease for nearly 2000 years, and probably longer, naturally possesses many features of medical interest, and it may not be out of place to-night, at the commencement of this meeting, to refer to certain phases of the evolution of Bath as a health resort, and to certain of the characters, medical and otherwise, who have played their part in its medical history.

EARLY DAYS.

Though the hot springs have been used in the treatment of disease ever since the Roman occupation, it was not till the middle of the sixteenth century that their therapeutic properties engaged the serious attention of the medical profession, and our knowledge of the actual practice of medicine in Bath remains very fragmentary till about the time of Queen Elizabeth, when its reputation as a resort for visiting patients first became established.

The primitive conditions, however, which obtained in the time of the late Tudors and early Stuarts were such that one imagines nothing but dire necessity would have caused anyone to visit Bath at that time. The town itself was one of the meanest in England, and the streets are said to have been a succession of dunghills, pigsties, and slaughter-houses. The baths themselves consisted of dilapidated, ill-kept, dirty pools, open to the air, and surrounded only by a low parapet, over which the more idle and inquisitive of the inhabitants were accustomed to view the proceedings at their ease and leisure. Men and women bathed together, naked, at nearly all times of the day and night, and disorder of all kinds was rampant. The baths are said to have resembled a veritable bear-garden, and cats, dogs, and even human bodies to have been hurled into the bath while people were bathing in it.

In spite of all the discomforts and positive dangers, Queen Anne of Denmark, the wife of James I., decided to take a course of baths in the bath known as the King's Bath. Unfortunately, Her Majesty had a somewhat alarming experience, as a ball of fire is said to have risen from her feet and spread out all over the surface of the bath. This remarkable phenomenon, which one can only suppose was an ebullition of marsh-gas rising from the mud, which was disturbed by the lady's feet, so alarmed the Queen that she refused to bathe there any more, and was with difficulty persuaded to finish her course of treatment in an adjoining bath, since known as the Queen's Bath, where she was assured such cataclysmic disturbances were never known to occur.

THE STUART COURT.

The reign of Charles II., however, marked the commencement of an entirely new phase in the history of the town. Whereas people had hitherto come solely for reasons of health, they now began to come for pleasure. In 1663 Charles II. formally removed his Court to Bath, and the concourse of people was so great that not only the town, but the surrounding villages also, were crowded with visitors. Though certain improvements had been effected in the conduct of the baths, and though quite a number of Bath physicians had by this time written more or less learned books on the action of the waters, the scene depicted in the print of the King's Bath in 1667 hardly suggests that balneological treatment was as yet regarded by the public with that respect which it deserved.

The proceedings appear to have been looked upon more as a popular entertainment than as a remedy for disease, and the antics of children diving for pennies, and of their elders indulging in fancy forms of swimming, appear to have afforded more amusement to the onlookers than to the unfortunate patients. The number of the latter, however, was steadily increasing, and included more particularly cases of rheumatism, gout, diseases of the skin, diabetes, dropsy, and paralysis. The reputation the waters had acquired for the treatment of sterility induced the Queen, Catherine of Braganza, to take a course of baths in the hope of providing an heir to the throne, and thereby regaining the waning affections of the errant and profligate Charles.

Besides the King and Queen, the Duke of York, and Prince Rupert, we learn that King Charles's somewhat Oriental *ménage* included Lady Castlemaine, the Duchess of Cleveland, and the Duchess of Portland, two others of Charles's acknowledged mistresses, and last but not least, the beautiful Miss Stewart. This pleasant little coterie, together with the rest of the Court, lodged, and apparently lived a somewhat hectic life, at a house known as Abbey House, adjoining the King's Bath.

DR. PIERCE AND DR. GUIDOTT.

Abbey House, known also as the Royal Lodgings, was owned by a Dr. Robert Pierce, the most successful practitioner in Bath of his day, and used by him as a sort of clinic to accommodate many of his more important patients.

Dr. Pierce, whose list of "Cures wrought by God's Blessing on the Directions of Robert Pierce, M.D.," shows him to have been a practical, painstaking, and careful physician, was evidently a firm believer in the proper selection of suitable cases for treatment at Bath. This is shown by his account of a certain Mrs. Frisby, sent to him from Northamptonshire, suffering from palsy and loss of speech, of whom he says:—

> "On bathing she apparently grew worse, especially in her speech, which very much discouraged her in proceeding farther. And indeed I was not very importunate with her for her longer stay, lest the Great Bell should have rung out for her here; for then inquiry would have been made, Whose Patient she was? Not what Distemper she had? or whether a due method had been used for her recovery; but with the Vulgar (who measure all things by the Success) the Physician that does not cure shall be sure to have the Reputation of killing the Patient that dies, be the disease or the patient never so much incurable. I return'd her back, therefore, to him that sent her hither, with advice to use Antiscorbuticks and Cephalicks, and never since heard anything of her."

The subject of after-treatment also received his most serious attention; one of his favourite prescriptions being a "sacculus," or in other words a muslin bag, containing various herbs, to be suspended in a barrel of beer.

Dr. Pierce's great rival was a Dr. Thomas Guidott, a distinguished graduate of Oxford, whose scientific bent induced him to carry out elaborate and painstaking researches on the chemical composition of the waters. Among his other activities he found time to write biographical accounts of all the doctors in Bath between the year 1600 and 1680. His biographies of some of the better known doctors of his time, such as Dr. Jorden, Dr. Bave, and Dr. Venner, show them to have been men of the highest integrity and professional attainments.

A GENERAL CASINO.

Though Queen Catherine of Braganza's hopes were not realised, her successor, Queen Mary of Modena, wife of James II., who bathed in the Cross Bath for a similar reason, was more fortunate, a son being born to her in the ensuing year. This was regarded as a most remarkable and convincing proof of the efficacy of the waters, and was suitably commemorated by placing an ornamental cross in the centre of the bath, with an appropriate inscription recording the circumstances.

Long before these events took place, however, the city had reached the acme of its fame, not only as the resort of the sick and ailing, but as the periodical visiting place of all who aspired to take any position whatever in the world of fashion. During the reign of Queen Anne, Bath became a sort of general casino for the whole kingdom. The Queen herself, who is said to have been such a martyr to gout that she was unable to stand during her coronation service, paid several visits, and for the next 120 years or more there is hardly a single person of distinction, from Royalty downwards, whose name is not in some way or another connected with visits to Bath, either for health or pleasure.

Thanks to the numerous authors and dramatists, such as Steele, Defoe, Goldsmith, Sheridan, Anstey, and others, who habitually visited Bath in the eighteenth century, the social habits and customs of this picturesque period are peculiarly well known to us. Whatever their other predilections may have been, we learn that the first and chief preoccupation of the majority of the company was the daily visit to the bath.

BATHS FOR DIVERSION.

In addition to those who took their baths under medical orders, many others bathed for diversion. The bath became a sort of fashionable parade which few cared to miss. The simple bathing dresses in vogue at the end of the seventeenth century were gradually replaced by more elaborate costumes, till eventually both men and women took to the water arrayed in the height of fashion. Ladies of distinction bathed in state, and were attended by the daughters of prominent citizens. Those who desired them were supplied with small floating trays, on which they placed nosegays, sweetmeats, snuff, and such trifles as face-powder and patches, to replace those dislodged by the moisture. The rule that the gentlemen should remain at one side of the bath and the ladies at the other seems to have been honoured more in the breach than in the observance. The patients were conveyed to and from the bath in sedan chairs, which in the case of the ladies were, to use the words of a contemporary French writer, "hermetically sealed when the occupants were old, ugly, or prudish, but artistically penetrable when they were finely formed."

Water-drinking, which by this time had become an established part of the treatment, took place later in the morning at the old Pump Room, which was replaced at the end of the century by the present structure. It was here that, to the accompaniment of a prodigious amount of gossip, scandal, and general disturbance, the prototypes of Lady Teazle, Lady Candour, and Mrs. Malaprop were to be found daily, drinking their quantum of water, and at the same time unsuspectingly providing Sheridan with the material for his plays.

The general régime and amusements of the patients, which after all constitute an important factor in their "cure," need only very brief reference. Fortunately we are able to get some idea of them, even if it is somewhat distorted, from the caricatures of Rowlandson and other cartoonists of the period. Following the parade in the Pump Room, public breakfasts formed an important feature. Later on in the day, after promenading in the parades, or adjourning to the various coffee-houses to hear the latest news, gambling, which in the time of the Georges was an almost universal passion, occupied the attention of the majority. Music, the drama, and art occupied the attention of the more intellectual of the company. Concerts were held daily, and it was while singing at one of those that the beautiful Miss Linley engaged the affection of the youthful and impetuous Sheridan.

CRITICS, FRIENDLY AND OTHERWISE.

The presence of such a large number of invalids from all parts of the country naturally attracted a great many doctors, many of whom practised in Bath during the season, and in London or elsewhere during the rest of the year. Amongst these there were probably a good many whose professional reputation and standard of ethics left something to be desired, and it is not surprising that in an age when wit, satire, and caricature were the predominant features in the literary world, they came in for their full share of ridicule and criticism. Thus Steele, writing in the *Guardian*, relates what he alleges to have been his own experience of the methods adopted for soliciting practice, saying:—

> "The physicians here are very numerous, but very good-natured. To these charitable gentlemen I owe that I was cured in a week's time of more distemper than I ever had in my life; they had almost killed me with their humanity. A learned fellow lodger presented me a little something on my first coming, to keep up my spirits; and the next morning I was so much enlivened by another, as to have an order to bleed me for my fever. I was proffered a cure for the scurvy by a third, and had a recipe for the dropsy gratis before night. In vain did I modestly decline these favours, for I was awakened early in the morning by an apothecary, who brought me a dose from one of my well-wishers. I paid him, but withal told him severely that I never took physic. My landlord hereupon took me for an Italian merchant that suspected poison; but the apothecary, with more sagacity, guessed that I was certainly a physician myself."

The most bitter criticism of the local doctors comes from Smollett, the author of "Peregrine Pickle" and "Roderick Random," both of which deal largely with the social life of Bath. Smollett himself was a doctor of medicine, and at one time essayed to practise in the town, and actually wrote a book on the external use of Bath waters. His lack of success appears to have roused feelings of intense bitterness against his more fortunate rivals, whom he describes as "a class of animals who live in the place, like so many ravens hovering round a carcass, and even ply for employment like scullers at Hungerford Stairs." In the circumstances, however, Smollett's virulent attacks on his own profession need hardly be taken too seriously, more especially as he shows a sordid tendency to paint all his characters in the most unfavourable light.

A more humorous parody on the ways of some at least of the Bath physicians of the eighteenth century is contained in Anstey's "New Bath Guide," which, in a series of letters, relates the adventures of a somewhat unsophisticated family during a visit to Bath for the sake of their health. In a letter to his mother, written on his arrival, Mr. Simpkin Blunderhead writes of his doctor:—

> "He determined our cases at length (God preserve us);
> I'm bilious, I find, and the women are nervous;
> Their systems relax'd, and all turned topsy turvy,
> With hypochondriacs, obstructions, and scurvy;
> And these are distempers he must know the whole on,
> For he talked of the peritoneum and colon."

According to Anstey, none of the doctors indulged in the baths they so freely prescribed for the patients, thus:—

> "Though many a skilful and learned physician,
> With candour, good sense, and profound erudition,
> Obliges the world with the fruits of his brain,
> Their nature and hidden effects to explain,
> Not one of the faculty ever has try'd
> These excellent waters to cure his own hide."

Though the criticisms of Steele, Smollett, and Anstey were probably throughly well deserved by those to whom they were directed, it must not be supposed that all the physicians in Bath were tarred with the same brush. On the contrary, many of them were men of the highest standing and repute, hardly to be distinguished, as Barbeau says, from the best of their colleagues in London. Among them may be specially mentioned Dr. Hartley, ranked by Coleridge with Milton, Newton, and Priestley; Dr. Cheyne, of whom Pope said there was no honester man or truer philosopher; Dr. William Oliver, a founder, and the first physician to the Mineral Water Hospital; Henry Harrington, renowned for his literary ability as well as for his knowledge of medicine; William Falconer, the physician to Pitt, who shares with Priestley the distinction of being the discoverer of oxygen. Last, but not least, of the eighteenth century physicians, we have Caleb Hillier Parry, who practised in Bath from 1780 to 1816, and whose contributions to medical literature, no less than his skill in practice, entitle him to rank as one of the most eminent physicians of his day.

LATER DEVELOPMENTS.

Though time will not allow of any references to the many distinguished Bath patients in the eighteenth century, one may specially mention John Hunter, who paid visits in 1777 and 1778 for the relief of pain associated with the aortic aneurysm which eventually caused his death. His condition being much worse in 1785, he hastened back to Bath, but became progressively worse, and died in London some months later. Though the vogue of Bath remained undiminished during the earlier years of the nineteenth century, important changes were gradually taking place in its fortunes, both from a social and medical point of view. Increasing facilities for travel and the wider diffusion of wealth began to lead people further afield, and Bath gradually lost its unique position as the chief, and in fact the only, resort of fashion in this country. On the medical side changes no less striking were also in progress. Balneological treatment began to be carried out on much more serious and rational lines. The promiscuous treatment of all types of patient in a common bathing pool, open to the gaze of an idle and inquisitive public, ceased with the erection, in 1798, of private suites of baths, which were the forerunners of the present installation, and in which various forms of treatment could be given to suit individual cases. The study of hydrology was being actively taken up, both in this country and on the continent of Europe.

The work of Dr. Currie of Liverpool, and later of Priessnitz in Silesia, called attention, in the first place, to the possibilities of effective treatment by the hot and cold application of ordinary water. Side by side with this development of hydrotherapy the study of the specific therapeutic properties of the various natural waters steadily advanced, till eventually that branch of therapeutics now known as medical hydrology may be said to have gradually emerged from a form of empiricism, based largely on tradition and superstitious belief, to a recognised branch of scientific medicine.

Fifty Years
OF
PROGRESS IN PUBLIC HEALTH.

Being the Presidential Address delivered to the Sanitary Science Section of the Congress of the Royal Sanitary Institute at Edinburgh on July 21st, 1925,

BY SIR GEORGE NEWMAN, K.C.B., M.D. EDIN., F.R.C.P. LOND.

[Sir George Newman introduced an eloquent address on the progress of public health during the past half century by detailing the various factors which culminated in the Public Health Act of 1875, considering these also in the light of future developments. He showed how enfranchisement of the town labourer in 1867, reform in the civil and military services, and the Education Acts were followed by further extensions of the franchise, which culminated in 1918, when the number of Parliamentary voters, now of both sexes, was trebled. He indicated the aspirations produced, as well as the *disappointments* which accompanied the liberal reforms, and referred particularly to the disease and despair which came in the train of the great industrial revolution. He showed how Chadwick's monumental "Survey" led to the Royal Commission on the Health of Towns and the Public Health Act of 1848, and how the influence of Bentham's utilitarian philosophy, of Owen, Cobbett and the Chartists, combined with the effects of the splendid reports of Simon to the Privy Council, and the work of Arnott, Kay, Southwood Smith and Greenhow to prepare the public for the developments to follow the Public Health Act of 1875.

Sir George Newman then sketched vividly the new influences after 1875, showing how two years after the passing of the Act the discovery of bacterial causes of disease revolutionised medical views and practice so that the centre of gravity turned from environment to infection "not only to the agents of infection but to the conditions of persons and environment, the lack of resistance which favoured those agents." There was a rapidly growing knowledge and sense of physiology which has continued to exert, during the last fifty years, an effect on the whole outlook of Preventive Medicine, while social emancipation has accompanied a rising standard of education and material comfort. It is now known that the chief defence against disease is not changed environment but the body of man, and secondly that obedience to the laws of physiology is necessary both for the maintenance of the body in health and for its full capacity and effective use.

The first section of the address closed with the statement that utilitarianism, environment, infection, physiology, and social emancipation have exerted an active influence in the past and are likely to achieve even more in the immediate future. Sir George Newman continued:—]

THE RESULTS OF THESE REFORMS.

Looking back from 1925, we may well ask, What has been the result? Well, first there has been a decline in the death-rate. In 1871–80 it was 21, and in 1924 it was 12; in the same period the infant mortality-rate, a most sensitive index of national health, was brought down from 149 per thousand born to 75. Expressed in another way, the expectation of life for every child born in Britain to-day is approximately 12 years longer than that of its grandfather.

The life-table published by Sir William Hamer in 1923 *gives the actual figures for London*:—

*London Life Table, 1841–1922.**

Period.	Expectation of life (years).		Period.	Expectation of life (years).	
	Males.	Females.		Males.	Females.
1841–50 ..	34·0	38·2	1891–1900 ..	41·2	45·4
1851–60 ..	36·4	40·4	1901–10 ..	47·2	51·9
1861–70 ..	35·7	39·0	1911–12† ..	49·5	54·5
1871–80 ..	38·0	42·4	1920–22 ..	53·8	59·1
1881–90 ..	40·1	44·5			

* Annual Report of London County Council, 1923, Ch. xxiii. and xxiv., Report of the County Medical Officer of Health, p. 13.

† The last pre-war years for which comparable figures are available.

Mr. W. Jones, the secretary of the Public Health Department of Glasgow, has recently shown that in 1870–72 the male infant born in that city had an "expectation" of 31 years, which in 1920–22 had been raised to 48 years, and the female infant had risen from 33 to 52 in the same period. It is significant that the "expectation" of life was better in Glasgow in 1821–27 than in 1870–72.

Then, in the second place, there has been a reduction in sickness and invalidity from certain diseases. In 1875 *enteric fever* accounted for 370 deaths in each million, last year the 370 had fallen to 12. Its incidence in the South African war was 28·5 per cent. of troops, in the European war 1 per cent. In 1875 there were 1500 deaths attributed to *typhus* in England and Wales (which had been differentiated from enteric in 1850); in 1924 there were only 5. But 100 years ago, in London and Edinburgh, typhus was endemic, with periodic epidemic outbursts. "The disappearance of typhus and relapsing fevers from the observation of all but a few medical practitioners in England, Scotland and Ireland," says Creighton, "is one of the most certain and most striking facts in our epidemiology," and he attributes their disappearance to better housing, cheap food, and increased wages. The *tuberculosis* death-rate is declining rapidly and with increasing velocity. In 1847 the death-rate per million from consumption was 3189, in 1875 it was 2313; and in 1924 it had fallen to 801. It is hardly too much to say that if this decline should continue more or less along the line it has followed, tuberculosis will have become a rare disease before the end of the present century.

Small-pox was a national scourge a century ago; to-day it is the perquisite of those who elect to have it. Last year Sir Clifford Allbutt declared that the almost complete abolition of *chlorotic anæmia* of young women is one of the most remarkable issues of a single generation of modern preventive medicine. All this has meant an immense saving of human life, an increase of human capacity and national wealth, an incalculable extension and enlargement of happiness and contentment.

But there is another epoch-making effect. The preventive medicine of 50 years has, in the words of Rudyard Kipling,

> "Smote for us a pathway
> To the ends of all the earth."

In some ways the most wonderful medical triumph of the past half century has been the discovery of the means of *the control of the tropics.* It is true that we are yet a long way off complete control, but the causes of disease have been found and the means of stamping them out demonstrated. *Famine* stands in the front line of the captains of the men of death—and the advance in methods of irrigation and transport of food have greatly reduced it and played a prominent part in the establishment of public health. Close behind famine follows disease. The discovery of the causes of malaria, of yellow fever, of plague, of cholera, and of sleeping sickness is common knowledge. Yet all these discoveries belong to the period since the Public Health Act of 1875.

Malcolm Watson demonstrated the possibility of preventing *malaria* in the Federated Malay States by banishing the anopheles' breeding places by the clearance of the coastal forest and subsoil and surface drainage. In India and elsewhere this technique may prove inexpedient or insufficient, unless supplemented by a direct attack on the mosquito in its larval or adult stage, or screening habitations or persons from its invasion, or treating cases or carriers. Indeed, the recent Malaria Commission of the League of Nations in Italy, Russia, and Eastern Europe has recommended for countries with incomplete public health services and limited funds the urgent necessity of abstaining from "radical" engineering measures and adopting "primary" public health measures of ascertainment of infection. treatment and after-treatment of patients and carriers, and dealing directly with infected houses and mosquitoes—in a word, quinine, the attack on the mosquito, the protection of the individual, and general sanitation.

The work of Gorgas in stamping out *yellow fever* in Havannah and on the Panama Isthmus is well known. By a strict discipline of quarantine, hospital isolation, drainage, sanitation, and mosquito screening and destruction, he was able to eliminate this disease, even though an immigration of non-immune population was continually occurring.

Practical measures against *sleeping sickness* (trypanosomiasis) have been taken effectually in the Cameroons, the Congo, Tanganyika, Kenya, and Uganda. They consist of the systematic surveys (clinical and bacteriological) of the infected population, followed by curative and prophylactic use of atoxyl in large doses; the separation of the healthy from the infected, with the isolation, if necessary, of whole villages or the migration of sections of the population from areas or streams affected with the tsetse-fly; sanitation of villages and improvement of diet; the clearance of banks of water-courses, paths, roads and settlements of all brushwood, and their proper drainage; and lastly, fly destruction by means of bird-lime or otherwise. These methods have completely suppressed sleeping sickness in the Portuguese Island of Principe, off the west coast of Africa, and proved effective in terminating recent disastrous epidemics on Lake Victoria Nyanza, and elsewhere in equatorial Africa. In this way hundreds of thousands of lives have been saved, and the way in which the tropics can be brought under control has been demonstrated. This problem of tsetse-fly is, in the opinion of the East African Commission (1925), "probably the most serious threat to the population in our East African territories. . . . We regard the tsetse domination as constituting a menace not merely to East Africa, but to all those countries which look to East Africa as the source of supply of food and raw materials."

All this can mean only one thing. The last half century has proved beyond doubt that nationally and imperially preventive medicine has now become practical politics. The trail has been blazed. It remains for this country to use it, apply it, and extend it—and all of it—with courage and wisdom, to its national and imperial problems as the sound and economic policy. A stunt here and a stunt there will not suffice—it should be organised as a whole, as an integral factor in state-craft.

The Future.

Let us turn to the future. Much remains to be done. For whilst progress has overcome many diseases, others remain prevalent and destructive. In 1924, in England and Wales, respiratory diseases caused 82,000 deaths, diseases of the heart and circulation 79,000, cancer 50,000, nervous diseases 47,000, tuberculosis 41,000, and influenza 19,000. These are very formidable enemies, responsible for 65 per cent. of our mortality, and we cannot yet defeat them. We still lose nearly 3000 mothers in childbirth, and more than 50,000 infants before they have completed their first year, and in both categories the maimed far outnumber the dead. We still have 40 per cent. of the deaths occurring under 50 years of age. In 1924 the sickness among insured persons only entailed more than 23 million weeks of lost work, equivalent to 447,000 years, or to 447,000 persons off work for a year. It is a very serious, and largely a preventable, drain upon national resources, costly and wasteful in many ways. In a word, national ill-health loses time and reduces production, as well as resulting in suffering, discontent, and premature death.

The history of the evolution of our system of public health since 1875, and its effects reveals, as we have seen, some of the chief influences which have played a predominant part. We must continue to be utilitarian in the best sense of the term. We must also be more economical. Our financial resources must be husbanded and our revenue not mis-spent or frittered away. I am convinced that the ratepayer is reasonable when he asks for equally good results at less total cost. In fact, it is now a national necessity that money must be saved and not wasted; production must be increased and not diminished; personal responsibility stimulated and not weakened.

But the *past teaches us we must still build upon a* sanitary foundation; we must, like Harvey, "search and study out the secrets of Nature by way of experiment," *and by research learn more of the hidden* paths of infective processes; we must teach and practise physiology; and above all, we must understand *the social habits, aspirations, and psychology* of the people. Yet for public practitioners of the science and art of preventive medicine all this is *not enough; it is not close enough down to the* business we have in hand. These high things must be harnessed in the statesmanship and technique of *health administration, and there seem to me to be* three main lines along which there is urgent need to advance.

1. A NEW LOCAL UNIT OF SANITARY GOVERNMENT.

The present system of local health government in England is like an Egyptian palimpsest, composed of several layers of design lying one upon the *other*. At the bottom there are the Poor-law unions, next above them and three times more numerous are the local sanitary authorities, superimposed upon which come the local education authorities (318), then the insurance committees numbering 145. Thus the whole country is mapped out four times over, but the charting has been done by different hands, at different times and for different purposes, and hence arises duplication, overlapping, and confusion. There is confusion in areas and authorities, but there is no less confusion in the family. There are four local authorities concerned with maternity and infancy; three with children of school age; five authorities deal with persons of unsound mind or mental deficiency; four authorities are concerned with "sick persons"; three with the aged poor; and four with the able-bodied poor. It is all anomalous, extravagant, and redundant, with a result which is ineffective and financially wasteful.

What we seem to need is, first, *a single unit of health government* with necessary subcommittees for particular purposes. The principles which should guide us in devising such a local authority are (*a*) the concentration, as far as practicable, in one authority in each area, of the responsibility for all administration of health services from local rates, with or without Exchequer grant in aid; (*b*) the association of the work of the Poor-law and insurance with the public health service, and the use by that service for the whole community of coördinated medical institutions both voluntary and municipal; and (*c*) the unification in appropriate committees of the local authority of all public medical provision for the sick and infirm of all ages. Clearly, there would be advantage in thus having one authority for all health purposes—and towards unification of this nature many are looking. But the question is large and complex, and there are many considerations to which regard must be paid in prescribing a unit of sanitary government, including its history, size, population, urbanisation, character of industry and society, intercommunication, rating, relation to local and central government, and so forth. *If a large local* unit be contemplated it would be necessary to provide for the encouragement of a consciousness of community of interest and aim in the *smaller* contributory or constituent divisions, with appropriate delegation of powers or functions in accordance with service to be rendered. The large *autonomous body* might in that way delegate some of the actual detail work to the more local bodies. There is a second, somewhat similar, common-sense requirement—*namely, uniformity of administration*—in all comparable areas. All through the country, and in all departments of State medicine, there is need for introduction *of accepted* standards and a larger measure of equalisation and uniformity of central and local action, yet with ample opportunity for variety dependent on local needs and circumstances. There remains a third principle which the profession must not allow itself to forget—namely, that the local unit of health government must be *representative* of the will of the people as a whole. It cannot be wholly medical in personnel or in purpose. It must be comprehensive and disinterested. "Our trade our politics" is never sound state-craft.

Now, in devising this reform the medical profession must, in the interest of the State not less than the profession, take their share, exchanging with the layman their views on many *points—the nature of the* authority, its membership, the question of the coöption of experts, finance, medical participation, *the respective functioning of the different* local committees, the use and adaptation of existing institutions and their economical arrangement, and the *place and character of the domiciliary* medical services.

The present scheme of local sanitary authorities was conceived *as far back as the Royal Sanitary* Commission of 1843, was actually recommended by the Commission of 1869 and legislated for in the Public *Health Act of 1872, which* established as many as 1590 local sanitary authorities in England and Wales, which now number 1857 (excluding the 63 counties). *Experience in health administration* and other forms of governance have proved the grave disadvantages of small units of local government, and the trend has *been to enlarge them.* The *Poor-law* Amendment Act of 1834 reduced the units of Poor-law administration from 10,500 to 600; the Education Act of 1902 reduced *the unit of education* administration from 2469 school boards to 318 local education authorities; the new Rating and Valuation Bill would reduce the *units of local rating* from 12,882 to 648. These reductions unquestionably make for efficiency and economy. The next step, and of its urgency there is *general agreement, is* to reduce the 1900 local health authorities in a similar drastic way, coördinating the duties of the smaller ones with those of the larger ones. *We must not forget* that the present scheme of local sanitary authorities (now 50 years old) has rendered great pioneer service and has given sanitation an *invaluable local setting*. But under modern conditions the disadvantages are overwhelming. In the smaller bodies there is all too often incompetency both of personnel and officers, combined with inadequacy of remuneration of the officers; there is duplication of officers and institutions leading to extravagances, *waste, and confusion;* local and personal considerations predominate, with the result that self-interest is cultivated, vested interest created, and public interest *neglected;* and there is lack of uniformity and equality in the administration of sanitary law common to the whole State. Yet epidemic disease spreads *through large communities* rather than small, and is not confined by parochial boundaries—e.g., it is impossible to grapple with small-pox or typhoid fever *if one small area differs from* another in the practice or neglect of essential methods. Water-supply, sewerage, river pollution, and hospital provision must also be dealt with on a general and not a particular scale. It is true, of course, that these features are characteristic of some of the smaller authorities only, but these *smaller* authorities are upwards of 1000 in number, and their disabilities are injuriously affecting the entire public health service of the nation. There are 1455 *posts of medical officer* of health, but only 350 of them are whole-time, so that 1100 medical officers of health are medical practitioners who, with all their goodwill, can *only* devote part of their time and energy to the public health service. Efficiency which is dependent upon the effect of divided loyalties or personal good nature can never be efficiency. In fact, it can only be, as Sir Lyon Playfair told the House of Commons in 1888, "desperately inefficient." "Wise men," said Sir John Simon long ago, "will not expect that a great national reform shall be achieved by casualties of good nature."

2. EFFECTIVE COÖRDINATION OF MEDICAL SERVICES.

I suggest that the second step in the future reform is the effective bringing together in each sanitary area of the various branches or forms of public medical service in such a way as to make them work as one connected and coöperative scheme. In science, as in war or in football, team-work is the condition of success. We must not only build on the foundations of others, but join hands with our own contemporaries. We have seen that historically the existing public medical services are the hospital, the Poor-law, factory supervision, the public health service (sanitary environment, infectious diseases, food-supply, and maternity), the school medical service and national health insurance.' The problem of the complete physical supervision of a people is thus met or nearly met. Maternity, infancy, the school-child, the worker, the insured person; poverty, sickness, and old age; and all through life the essentials of a healthy environment—these things are now all separately provided for. But there are three outstanding defects. First, the provision made is as yet incomplete and inadequate; secondly, no provision is organised by law for children between infancy and school age, or for adolescents from 14 to 16 years of age (between the end of school life and the beginning of insurance); and thirdly, though we have six public medical services, there is not a sanitary area in the country in which we are at present getting full inter-coördination or even unification of administration. There is far too much of the water-tight compartment, and too many different authorities working the services. Yet until there is linking up and concentration of all forces on the focal point, it is idle to expect full effect. Though we have in England and Wales upwards of 3400 hospital institutions with 350,000 beds, there is but little correlation between Poor-law, isolation, voluntary, or special diseases hospitals. Yet in each district there should be close association under one authority between voluntary and State institutions. Though the Poor-law is now so largely medical, it is still administered on a relief basis and by bodies which are not health authorities. The factory service and the school medical service are still insufficiently connected with the local work of the sanitary authority; and above all, there is much to be done to give health insurance its rightful place as an integral factor in preventive medicine.

The great triumphs of public health work in the last century were for the most part won in the field of environmental hygiene and it must always remain our foundation. With the new century, however, there came a remarkable development. A direct frontal attack was made upon tuberculosis, a comprehensive system of school hygiene was introduced and rapidly developed, maternity and child welfare work was widely undertaken, the new knowledge of the diagnosis and treatment of venereal disease was applied gratuitously for the alleviation of sufferers all over the country, and by the establishment of the insurance medical service the State made the family doctor an integral part of our system of public health administration. It may well be that from a public health point of view it would have been more convenient if Poor-law reform had preceded the establishment of national health insurance, and if the latter had been anchored in a reorganised sanitary authority closely associated with clinics and hospital institutions. But there it is: in Britain we are not deductive philosophers, and we proceed, from precedent to precedent, "to take occasion by the hand." The fundamental fact and common ground is this, that we have in Great Britain 15,000 insurance practitioners who have entered the service of the State to care for the health of upwards of 14,000,000 insured persons in the interest of preventive medicine in its broadest meaning. The reform which our forerunners desired has come to pass, the workers have ready access to the doctor at the earliest stage of disease, with the result that the medical supervision of them is actually threefold greater than before the Insurance Act was passed. There is more careful diagnosis; there is earlier treatment; there is better knowledge of the incidence and distribution of disease, and at a stage when it can be cured or prevented; there is, for the first time, a measurement of the relation between sickness and capacity to work. No doubt there are still many defects and inequalities in the administration of so novel a scheme. But the scheme is here; and it is for us all to make it work by integrating it with the other public medical services. If in every district medical practitioners and the medical officer of health will coöperate cordially an immeasurable advance will be made forthwith.

3. PUBLIC EDUCATION IN HEALTH.

The third reform which is needed seems to be proceeding apace—namely, the education of the people in hygiene. One thing is quite certain. We have reached a stage in the evolution of the public health when it is a necessity of further progress that we should create an enlightened public opinion and carry it with us. This is necessary, first, because there is need of an "impulse" behind sanitary legislation and effective administration of it, and secondly, because the public health is dependent upon personal hygiene and the day by day individual practice of the principles of preventive medicine. We must do more for ourselves.

All local authorities are indirectly engaged in educational health work in so far as they discharge effectually their statutory duties under the Public Health Acts, and this aspect of their work is exerting, as a study of the history of the past 50 years will show, a paramount influence on the community. It is, on the whole, the most effective and far-reaching form of health education. Some local authorities and many voluntary societies are undertaking supplementary educational work of a more direct nature, and under the new Public Health Bill of this year all authorities outside London are to be given definite and wide powers to develop this service. Section 67 is as follows:—

> "Any local authority or county council may arrange for the publication within their area of information on questions relating to health or disease, and for the delivery of lectures and the display of pictures in which such questions are dealt with, and may defray the whole or a portion of expenses incurred for any of the purposes of this section."

It will no doubt be necessary before long to consider whether this work should be included in the grant-earning services, and if so whether, and on what terms, voluntary societies engaged in health propaganda should be similarly assisted. As we are evidently on the brink of a widening system of popular health instruction, I may express the considered opinion that it is the local authorities who should be mainly responsible for undertaking systematic educational health work, direct as well as indirect, suitable to their own district circumstances, and needs, with such supplementary assistance as the voluntary societies concerned may find themselves able to furnish.

It is important that information thus afforded should be appropriate, correct, and timely. Some medical knowledge should be imparted, some knowledge of the ways and means of sanitary government, and much advice as to personal hygiene—but not one of these three should be overloaded. Exceptional facilities now exist, and the people should be encouraged to use them. Instruction should be given as to the effect of social habits and conditions on health, and *that it is won by a way of life* rather than a bottle of medicine. Above all, we must all learn to think of public health, not only in terms of the individual, the home or the parish, but nationally, Imperially, and even Internationally. The world is both larger and smaller than in 1875, and the capacities and opportunities of human life and endeavour have been greatly and hopefully expanded.

THE

Croonian Lectures

ON SOME

DISORDERS OF MOTILITY AND OF MUSCLE TONE,

WITH SPECIAL REFERENCE TO THE CORPUS STRIATUM.

Delivered before the Royal College of Physicians of London

BY S. A. KINNIER WILSON, M.D., B.SC. EDIN., F.R.C.P. LOND.,

PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE; JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

LECTURE III.*

PLASTICITY: "LENGTHENING AND SHORTENING" REACTION.

MR. PRESIDENT AND GENTLEMEN,—The proof of the existence of the property of plasticity in muscle tone we owe to the investigations of Sherrington, who in his work on experimental decerebrate rigidity discovered that the limb of the animal, when passively flexed, say at the knee, would retain that posture, the stretched quadriceps adapting itself to the new position of the limb and holding it so ("lengthening" reaction); conversely, if the latter was again extended, the quadriceps naturally shortened, yet again contributed its quota to maintenance of the fresh attitude ("shortening" reaction). We note that in Sherrington's view this quality belongs to tone as derived entirely from somatic proprioceptive arcs, and that it is demonstrated only in pathological (decerebrate) states, in which one need scarcely say various efferent paths *both* from the cortex *and* the basal ganglia are completely out of action.

In the course of my study of striatal cases much attention has been directed to the question of plasticity, and *the general conclusion is, that this quality of muscle tone is not specially in evidence in these diseases.* Parkinsonian limbs, passively compelled to assume a certain posture, reveal no particular tendency to maintenance of the new position. On the contrary, when left to themselves they tend to return forthwith to the Parkinsonian attitude from which they have been disturbed, that is, if the case is of average severity. A patient told me spontaneously of his frequent observation when in bed that on his extending his arms outside the bedclothes they always came back insensibly to a position near the upper part of his chest. This return to previous attitude is easily observable in the case of the hand and fingers; passive extension of the fingers is not succeeded by maintenance of the extended posture, even for as short a time as a second or two, whereas in decerebrate preparations the fresh posture is held almost indefinitely.

The feature of maintenance of different postures passively imposed on a limb is characteristic of the clinical state known as catatonia, and is not in itself dependent on the presence of extremes of rigidity. Catatonia is seen in a considerable number of morbid clinical conditions, diverse in nature but alike in that cortical function is disordered. For example, it is often noticed in the acute stages of epidemic encephalitis, it is a pronounced feature of various psychoses, of certain cases of hysteria, and so on. In respect of outward character, the "lengthening and shortening" reaction of a decerebrate limb does not differ from that seen in any of the above-mentioned morbid states, in which, precisely, the limb muscles, in virtue of plasticity, hold it in any posture passively impressed on it. The argument is not vitiated by any claim that in these cortical and "psychical" conditions the action of "volition" is not excluded, for investigation will prove the claim to be unfounded. Now in my experience no clinical state resembling catatonia, even if merely in *external* characters, occurs in ordinary *cases belonging to the striatal group.* Applying the usual clinical tests, the observer finds little evidence of the occurrence of any reaction to be appropriately described as a "lengthening and shortening" reaction, such as Walshe, for instance, has had occasion to note in a case of decerebrate rigidity in man, and Royle, in spastic paraplegia of cortical origin (gunshot wound). I cannot therefore give any support to the view of Hunter, as expressed in his latest articles, that "a tendency for fixation of the muscle at any length passively imposed upon it" is a special characteristic of Parkinsonian rigidity. On the contrary, the cases in which it has come under my notice have been definitely extrastriatal. In view of its interest, allusion may be made to a case of my own.

The patient was an elderly man who was admitted to hospital in a semi-conscious state, with a history of having had a "stroke" 24 hours previously. On examination the right arm was seen to be in a state of "early rigidity" and in moderate flexion; the right leg was similarly rigid and extended. Aphasia was prominently in the foreground of the clinical picture. The man frequently passed his left arm over his head or moved it spontaneously about the bed, whereas the right limbs exhibited no such movements. The deep reflexes were more active on the right than on the left; the plantars were both in reduced flexion, and a crossed plantar in flexion was constantly obtained *from the right* sole, but never vice versâ.

It was remarked at once on testing that the right limbs (arm and leg) exhibited the "lengthening and shortening" reaction in a pronounced form; as a single illustration, when the patient was put on his left side, the right lower extremity was passively abducted at the hip and flexed to a right angle at the knee, and this new (and awkward) posture was *maintained for three minutes* by the watch. The leg was then extended at the knee, and the quadriceps group at once maintained the extension again. The left limbs showed a similar reaction in a less noticeable degree; it was usually and more or less immediately interrupted by the "spontaneous" movements already alluded to.

On the second day the patient had two typical Jacksonian fits on the right side, beginning with twitching of the right arm, and both of these spread in moderate degree to the "second side." A diagnosis of cortical (submeningeal) hæmorrhage over the left frontoparietal region was made and this was corroborated by subsequent examination.

A case of this kind confirms the general statement made above, to the effect that the type of clinical case most likely to furnish proof of the existence of plasticity as a quality or property of muscle tone is one in which pyramidal function is disordered from the cortical side.

Passing reference may at this point be allowed to the experimental evidence on which Hunter partly relies for support of his views. In the domestic fowl and the seagull he removed the corpus striatum on one side and obtained a diffuse muscular rigidity, which he says "is remarkably similar to Parkinsonian rigidity in man. Its diffuseness, resistance to stretching, and the tendency for fixation of the muscle at any length passively imposed on it, are common to the two conditions." Now it may be fairly argued that the bird is not a suitable animal for experiments on the corpus striatum from which deductions are to be drawn as to striatal function *in man*, for the plain reason that it has practically no cerebral hemisphere beyond the corpus striatum; its pallium is electrically inexcitable; it has no pyramidal tracts in the ordinary sense; in its tractus striomesencephalicus (spared by the operator) mingle fibres both of striate origin and from the minute extrastriate pallium. The differences between it and

2. EFFECTIVE COORDINATION OF MEDICAL SERVICES.

I suggest that the second step in the future reform is the effective bringing together in each sanitary area of the various branches or forms of public medical service in such a way as to make them work as one connected and coöperative scheme. In science, as in war or in football, team-work is the condition of success. We must not only build on the foundations of others, but join hands with our own contemporaries. We have seen that historically the existing public medical services are the hospital, the Poor-law, factory supervision, the public health service (sanitary environment, infectious diseases, food-supply, and maternity), the school medical service and national health insurance. The problem of the complete physical supervision of a people is thus met or nearly met. Maternity, infancy, the school-child, the worker, the insured person; poverty, sickness, and old age; and all through life the essentials of a healthy environment—these things are now all separately provided for. But there are three outstanding defects. First, the provision made is as yet incomplete and inadequate; secondly, no provision is organised by law for children between infancy and school age, or for adolescents from 14 to 16 years of age (between the end of school life and the beginning of insurance); and thirdly, though we have six public medical services, there is not a sanitary area in the country in which we are at present getting full intercoördination or even unification of administration. There is far too much of the water-tight compartment, and too many different authorities working the services. Yet until there is linking up and concentration of all forces on the focal point, it is idle to expect full effect. Though we have in England and Wales upwards of 3400 hospital institutions with 350,000 beds, there is but little correlation between Poor-law, isolation, voluntary, or special diseases hospitals. Yet in each district there should be close association under one authority between voluntary and State institutions. Though the Poor-law is now so largely medical, it is still administered on a relief basis and by bodies which are not health authorities. The factory service and the school medical service are still insufficiently connected with the local work of the sanitary authority; and above all, there is much to be done to give health insurance its rightful place as an integral factor in preventive medicine.

The great triumphs of public health work in the last century were for the most part won in the field of environmental hygiene and it must always remain our foundation. With the new century, however, there came a remarkable development. A direct frontal attack was made upon tuberculosis, a comprehensive system of school hygiene was introduced and rapidly developed, maternity and child welfare work was widely undertaken, the new knowledge of the diagnosis and treatment of venereal disease was applied gratuitously for the alleviation of sufferers all over the country, and by the establishment of the insurance medical service the State made the family doctor an integral part of our system of public health administration. It may well be that from a public health point of view it would have been more convenient if Poor-law reform had preceded the establishment of national health insurance, and if the latter had been anchored in a reorganised sanitary authority closely associated with clinics and hospital institutions. But there it is: in Britain we are not deductive philosophers, and we proceed, from precedent to precedent, "to take occasion by the hand." The fundamental fact and common ground is this, that we have in Great Britain 15,000 insurance practitioners who have entered the service of the State to care for the health of upwards of 14,000,000 insured persons in the interest of preventive medicine in its broadest meaning. The reform which our forerunners desired has come to pass, the workers have ready access to the doctor at the earliest stage of disease, with the result that the medical supervision of them is actually threefold greater than before the Insurance Act was passed. There is more careful diagnosis; there is earlier treatment; there is better knowledge of the incidence and distribution of disease, and at a stage when it can be cured or prevented; there is, for the first time, a measurement of the relation between sickness and capacity to work. No doubt there are still many defects and inequalities in the administration of so novel a scheme. But the scheme is here; and it is for us all to make it work by integrating it with the other public medical services. If in every district medical practitioners and the medical officer of health will coöperate cordially an immeasurable advance will be made forthwith.

3. PUBLIC EDUCATION IN HEALTH.

The third reform which is needed seems to be proceeding apace—namely, the education of the people in hygiene. One thing is quite certain. We have reached a stage in the evolution of the public health when it is a necessity of further progress that we should create an enlightened public opinion and carry it with us. This is necessary, first, because there is need of an "impulse" behind sanitary legislation and effective administration of it, and secondly, because the public health is dependent upon personal hygiene and the day by day individual practice of the principles of preventive medicine. We must do more for ourselves.

All local authorities are indirectly engaged in educational health work in so far as they discharge effectually their statutory duties under the Public Health Acts, and this aspect of their work is exerting, as a study of the history of the past 50 years will show, a paramount influence on the community. It is, on the whole, the most effective and far-reaching form of health education. Some local authorities and many voluntary societies are undertaking supplementary educational work of a more direct nature, and under the new Public Health Bill of this year all authorities outside London are to be given definite and wide powers to develop this service. Section 67 is as follows:—

> "Any local authority or county council may arrange for the publication within their area of information on questions relating to health or disease, and for the delivery of lectures and the display of pictures in which such questions are dealt with, and may defray the whole or a portion of expenses incurred for any of the purposes of this section."

It will no doubt be necessary before long to consider whether this work should be included in the grant-earning services, and if so whether, and on what terms, voluntary societies engaged in health propaganda should be similarly assisted. As we are evidently on the brink of a widening system of popular health instruction, I may express the considered opinion that it is the local authorities who should be mainly responsible for undertaking systematic educational health work, direct as well as indirect, suitable to their own district circumstances, and needs, with such supplementary assistance as the voluntary societies concerned may find themselves able to furnish.

It is important that information thus afforded should be appropriate, correct, and timely. Some medical knowledge should be imparted, some knowledge of the ways and means of sanitary government, and much advice as to personal hygiene—but not one of these three should be overloaded. Exceptional facilities now exist, and the people should be encouraged to use them. Instruction should be given as to the effect of social habits and conditions on health, and *that it is won by a way of life* rather than a bottle of medicine. Above all, we must all learn to think of public health, not only in terms of the individual, the home or the parish, but nationally, Imperially, and even internationally. The world is both larger and smaller than in 1875, and the capacities and opportunities of human life and endeavour have been greatly and hopefully expanded.

THE

Croonian Lectures

ON SOME

DISORDERS OF MOTILITY AND OF MUSCLE TONE,

WITH SPECIAL REFERENCE TO THE CORPUS STRIATUM.

Delivered before the Royal College of Physicians of London

BY S. A. KINNIER WILSON, M.D., B.Sc. EDIN.,
F.R.C.P. LOND.,
PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE; JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

LECTURE III.*

PLASTICITY: "LENGTHENING AND SHORTENING" REACTION.

MR. PRESIDENT AND GENTLEMEN,—The proof of the existence of the property of plasticity in muscle tone we owe to the investigations of Sherrington, who in his work on experimental decerebrate rigidity discovered that the limb of the animal, when passively flexed, say at the knee, would retain that posture, the stretched quadriceps adapting itself to the new position of the limb and holding it so ("lengthening" reaction); conversely, if the latter was again extended, the quadriceps naturally shortened, yet again contributed its quota to maintenance of the fresh attitude ("shortening" reaction). We note that in Sherrington's view this quality belongs to tone as derived entirely from somatic proprioceptive arcs, and that it is demonstrated only in pathological (decerebrate) states, in which one need scarcely say various efferent paths *both* from the cortex *and* the basal ganglia are completely out of action.

In the course of my study of striatal cases much attention has been directed to the question of plasticity, and *the general conclusion is, that this quality of muscle tone is not specially in evidence in these diseases.* Parkinsonian limbs, passively compelled to assume a certain posture, reveal no particular tendency to maintenance of the new position. On the contrary, when left to themselves they tend to return forthwith to the Parkinsonian attitude from which they have been disturbed, that is, if the case is of average severity. A patient told me spontaneously of his frequent observation when in bed that on his extending his arms outside the bedclothes they always came back insensibly to a position near the upper part of his chest. This return to previous attitude is easily observable in the case of the hand and fingers; passive extension of the fingers is not succeeded by maintenance of the extended posture, even for as short a time as a second or two, whereas in decerebrate preparations the fresh posture is held almost indefinitely.

The feature of maintenance of different postures passively imposed on a limb is characteristic of the clinical state known as catatonia, and is not in itself dependent on the presence of extremes of rigidity. Catatonia is seen in a considerable number of morbid clinical conditions, diverse in nature but alike in that cortical function is disordered. For example, it is often noticed in the acute stages of epidemic encephalitis, it is a pronounced feature of various psychoses, of certain cases of hysteria, and so on. In respect of outward character, the "lengthening and shortening" reaction of a decerebrate limb does not differ from that seen in any of the above-mentioned morbid states, in which, precisely, the limb muscles, in virtue of plasticity, hold it in any posture passively impressed on it. The argument is not vitiated by any claim that in these cortical and "psychical" conditions the action of "volition" is not excluded, for investigation will prove the claim to be unfounded. Now in my experience no clinical state resembling catatonia, even if merely in *external* characters, occurs in ordinary cases belonging to the striatal group. Applying the usual clinical tests, the observer finds little evidence of the occurrence of any reaction to be appropriately described as a "lengthening and shortening" reaction, such as Walshe, for instance, has had occasion to note in a case of decerebrate rigidity in man, and Royle, in spastic paraplegia of cortical origin (gunshot wound). I cannot therefore give any support to the view of Hunter, as expressed in his latest articles, that "a tendency for fixation of the muscle at any length passively imposed upon it" is a special characteristic of Parkinsonian rigidity. On the contrary, the cases in which it has come under my notice have been definitely extrastriatal. In view of its interest, allusion may be made to a case of my own.

The patient was an elderly man who was admitted to hospital in a semi-conscious state, with a history of having had a "stroke" 21 hours previously. On examination the right arm was seen to be in a state of "early rigidity" and in moderate flexion; the right leg was similarly rigid and extended. Aphasia was prominently in the foreground of the clinical picture. The man frequently passed his left arm over his head or moved it spontaneously about the bed, whereas the right limbs exhibited no such movements. The deep reflexes were more active on the right than on the left; the plantars were both in reduced flexion, and a crossed plantar in flexion was constantly obtained from the right sole, but never vice versâ.

It was remarked at once on testing that the right limbs (arm and leg) exhibited the "lengthening and shortening" reaction in a pronounced form; as a single illustration, when the patient was put on his left side, the right lower extremity was passively abducted at the hip and flexed to a right angle at the knee, and this new (and awkward) posture was maintained for three minutes by the watch. The leg was then extended at the knee, and the quadriceps group at once maintained the extension again. The left limbs showed a similar reaction in a less noticeable degree; it was usually and more or less immediately interrupted by the "spontaneous" movements already alluded to.

On the second day the patient had two typical Jacksonian fits on the right side, beginning with twitching of the right arm, and both of these spread in moderate degree to the "second side." A diagnosis of cortical (submeningeal) hæmorrhage over the left frontoparietal region was made and this was corroborated by subsequent examination.

A case of this kind confirms the general statement made above, to the effect that the type of clinical case most likely to furnish proof of the existence of plasticity as a quality or property of muscle tone is one in which pyramidal function is disordered from the cortical side.

Passing reference may at this point be allowed to the experimental evidence on which Hunter partly relies for support of his views. In the domestic fowl and the seagull he removed the corpus striatum on one side and obtained a diffuse muscular rigidity, which he says "is remarkably similar to Parkinsonian rigidity in man. Its diffuseness, resistance to stretching, and the tendency for fixation of the muscle at any length passively imposed on it, are common to the two conditions." Now it may be fairly argued that the bird is not a suitable animal for experiments on the corpus striatum from which deductions are to be drawn as to striatal function *in man*, for the plain reason that it has practically no cerebral hemisphere beyond the corpus striatum; its pallium is electrically inexcitable; it has no pyramidal tracts in the ordinary sense; in its tractus striomesencephalicus (spared by the operator) mingle fibres both of striate origin and from the minute extrastriate pallium. The differences between it and the mammalian brain are great enough to render comparisons as to function more than usually precarious. (The data are more specifically examined in a paper on an "Experimental Research into the Anatomy and Physiology of the Corpus Striatum," published in 1914.)

---

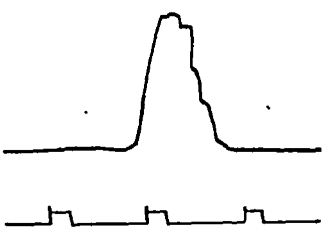
* Lectures I. and II. appeared in THE LANCET of July 4th and 11th respectively.

Since in the sense employed by Sherrington the reaction of plastic tone is a property of ordinary somatic proprioceptive tone, and since hypertonia characterises paralysis agitans and the other diseases at present under discussion, we might expect to be able to demonstrate at least minor degrees of the "lengthening and shortening" reaction in these affections. The well-recognised distinctions, however, between pyramidal and extrapyramidal cases must be borne in mind; prominent here is the fact that nothing like the same diminution of "voluntary" innervation obtains in the latter as in the former. Speaking generally, the subject of paralysis agitans is capable of innervating his musculature to an extent impossible in the patient whose corticospinal tract or tracts are anatomically or physiologically interrupted, and for this reason, as I consider, the lesions in his case cannot produce the pathological conditions essential for the visible demonstration of the phenomena of plasticity in any marked degree. In other words, the more serious the interruption of the pyramidal system, the more easily is this particular tone reaction excited; and it is seen at its maximum when that system is completely in abeyance, as in decerebration.

THE "COGWHEEL" PHENOMENON.

We may now consider whether the "cogwheel" symptom of Camillo Negro (1901) is connected with the reaction in question, and whether it may be regarded as a minor degree of the "lengthening and shortening" sign. When a hypertonic muscle is passively stretched it resists; and this resistance often takes the form of an irregular jerkiness, as though the muscle were being pulled out over a ratchet arrangement; it is momentarily checked and extended in a little alternating series of two, three, or more phases, hence the expression imagined by Negro. If the passive stretching is quick the phenomenon is usually more readily appreciated by the examiner. (Cf. Figs. 21 and 22.) It is not found in the opposite muscle that is being simultaneously shortened; on active ("voluntary") movement it may be remarked both in the contracting and the relaxing muscles, but, I find, to a less extent than in the case of passive movement.

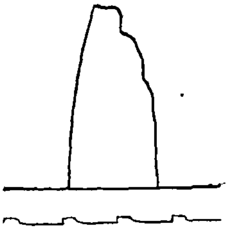
FIG. 22.



Passive stretching of triceps in a case of paralysis agitans. "Cogwheel" sign.

Various and very different explanations have been forthcoming. Santos, for instance, an exponent of the dual theory of muscle tone, ascribes it to a clonus of the parasympathetically innervated part of muscle, but if Hunter's opinion that this part is compact of non-contractile fibres be adopted it is at once obvious these cannot of themselves be the seat of any such movement, for *ex hypothesi* they are only passively moved with the contracting fibres. Bing, who remarks that this view does not account for the occurrence of a degree of the "cogwheel" sign in active movement, seeks to explain it as a disturbance of reciprocal innervation, a release-phenomenon "produced by failure of a subcortical mechanism which ensures continuity of decontraction." It is simpler, I consider, to regard it as one of the expressions of hyperactivity on the part of somatic proprioceptive arcs. When a muscle already in contraction (hypertonia) is abruptly stretched its end-organs are stimulated and the reflex contraction promptly reinforced, thus offering a momentary increase of resistance, felt as a sort of "catch" in the passive extension; the moment this "catch" takes place there is an immediate tendency for fixation at that point, for the muscle, being in a condition of postural overtone, will exhibit this tendency whenever it is momentarily "pulled up" (movement being the process of changing from one posture to another). In its turn the "catch" is overcome by the examiner's effort and the stretching causes a second excitation of the arc, hence again the process is gone through. If a muscle, however hypertonic, is slowly pulled out the phenomenon is so faint as to be negligible. In a sense, therefore, the "cogwheel" phenomenon may be regarded as a minor form of the "lengthening and shortening" reaction. It is not, however, confined to Parkinsonian and similar cases, though naturally more readily there demonstrable because the muscle can in fact be stretched; in severe hemiplegic cases the rigidity may not be overcome by stretching, but when it can be the observer is sometimes conscious of a mild "cogwheel" movement. Its appearance in the course of active or "voluntary" movement of a rigid motor unit (in protagonists and antagonists) is less noticeable than during passive movement; I have not been able to satisfy myself that it is much in evidence in "voluntary" shortening, but it may be occasionally felt in "voluntary" lengthening in Parkinsonian cases (Fig. 23), where the explanation cannot be essentially dissimilar. If denervation or decontraction is not prompt enough the transient check brings about the same result because of the hypertonia.

FIG. 23.



"Voluntary" lengthening of biceps in a case of post-encephalitic Parkinsonism. Slight "cogwheel" phenomenon.

STRIATAL ATTITUDE.

So familiar and definite are the attitudes adopted in average cases of Parkinsonism (of whatever origin) and of progressive lenticular degeneration that no detailed account is required. Parkinsonian patients, young or old, all look like each other, mainly if not solely because of the "involuntary" assumption of more or less identical postures, which are at least as specific as those of hemiplegia. The attitude is one of generalised flexion, as a rule; the lower extremities are as it were folded in moderate flexion at ankle, knee, and hip; the trunk is flexed in a concave anterior curve; the head is commonly flexed; the upper limbs are semiflexed at the elbows. At the wrists, however, extension ordinarily occurs, with flexion at the metacarpo-phalangeal and usually also at the interphalangeal joints. Very occasionally, as is not well enough known, a type of Parkinsonism with extension of head and trunk is met with.

Posture or attitude cannot be considered apart from tone-effecting mechanisms. Tone is posture; that is to say, in toneless limbs no particular posture can develop, except as caused by extrinsic agencies —e.g., gravity. Limbs whose musculature is in tone (reflex contraction) assume postures capable in the normal person of being modified instanter at the bidding of "volition," whereas in disease (pyramidal and extrapyramidal) tone-postures are a sequel to release from the control of superior, tone-controlling centres. The postural scheme of the hemiplegic is no haphazard thing; a predilection type or pattern exists, possible explanations of which have been examined in my paper on "The Old Motor System and the New." In decerebration, analogously, a selective incidence of tone on the antigravity muscles takes place. These specific postures can only be assumed if at the same time the inflow of tone to antagonistic groups is relatively lessened by reflex inhibition. In the case of hemiplegia, tone influx is divided; in the arm, the flexor groups are hypertonic, in the leg the extensors. It is interesting and no less important to note that in each instance the groups with lessened tone are the weak muscles (e.g., the flexors, in the leg). From what has already been said of the blending of tone with muscular contractions otherwise evoked this can be readily appreciated.

Now in the case of Parkinsonian posture the circumstances differ somewhat; there is not the same "schizotonia" (to borrow a useful term recently coined by Dusser de Barenne) as in pyramidal and decerebrate conditions. The feature of paralysis agitans and kindred morbid states, from this standpoint, is the apparently indifferent or diffuse distribution of the hypertonia, as has been made the subject of allusion already. But if the increase of tone were strictly equal in each and every skeletal group of prime *movers and antagonists, I do not see why resumption of postures as definite and specific as the Parkinsonian* should take place after they are passively or actively disturbed. We are forced to the conclusion that, *general hypertonia notwithstanding, it preponderates* in flexor as opposed to extensor muscles; more precisely, in those groups (already specified) whose contraction underlies the maintenance of Parkinsonian attitudes.

On examination these muscles are seen to be firm, to have shape, and to be outlined in contraction with a distinctness as manifest as in hemiplegic groups associated with posture, and I cannot therefore agree with Hunter that in Parkinsonian rigidity there is no selective incidence, or with his corollary that only contractile tone (in his sense) is thus selective. Nor can I confirm his view that "the posture assumed in Parkinsonian rigidity is due to plastic tone *only* [italics mine], exhibited in agonists and antagonists." On his own hypothesis plastic tone is due to *non-contractile* fibres moved passively by contracting fibres and subsequently held thus in posture, hence the latter must first be in activity, and plastic tone of *itself can do no more than* support a tone-scheme previously and otherwise brought about. To exclude contractile tone, therefore, in so plain an attitude as the Parkinsonian seems impossible as well as unnecessary; finally, if plastic tone is exhibited *indifferently* in agonists and antagonists, the adoption of a specific posture is *unexplained*.

Of the specificity of Parkinsonian attitude there can be, in my opinion, no question whatever, but I can offer at present no satisfactory explanation of its type. No merely mechanical preponderance, as it were, of flexor over extensor contraction suffices. Hughlings Jackson drew contrasts between Parkinsonian and cerebellar attitudes, and I have myself endeavoured in other communications to seek a solution. Possibly weight should be laid *on the* contrast between the relative incidence of tone in decerebrate cases on the extensor or antigravity musculature ("reflex standing"), and in paralysis agitans on the flexor musculature. But the "meaning" of the latter posture is obscure. In any case, as I have argued elsewhere, the tone-picture of Parkinsonism is absolutely distinct from that of double hemiplegia; yet in decerebrate cases that of the latter is more closely approached than the tone-picture of the *former, although* the corpus striatum is just as completely out of action. The inferences to be drawn from these data are discussed at some length in my paper on "The Old Motor System and the New."

"FIXATION-CONTRACTION."

Much attention has been devoted, more especially by continental workers, to the question of the occurrence of what is called "fixation-contraction" in cases of striatal *disease*. The term is not familiar to English neurologists, but the condition has long been known under the name of "Westphal's paradoxical contraction," and consists typically of an involuntary (reflex) contraction of a muscle, *of a slow and tonic character, when its ends are passively* approximated as closely as is practicable. In suitable instances it can be demonstrated in the tibialis anticus muscle by firm passive dorsiflexion of the foot, and this "tibialis phenomenon" was obtained years ago by Oppenheim in cases of paralysis agitans. In 1900 Foerster stated that "fixation-contraction" can be seen in *all* the muscles in that disease, as well as in cases of arterio-sclerotic muscular rigidity. It has been called "fixation-rigidity" by Strümpell. Jakob, also, attributes considerable importance to the phenomenon.

In routine examination of numerous examples of the various morbid affections that at present concern us special attention has been given to "fixation-contraction," following the technique of Foerster, who says the passive movement (of shortening) has to be made with a certain jerk and the limb segment pressed firmly to the end-position, the head of the bone concerned being pushed well into its socket, and the new position held passively for an appreciable moment. When this technique is prosecuted the muscle passively shortened exhibits a tonic contraction *analogous to the "shortening reaction"* already investigated as a property of somatic proprioceptive tone.

As a result of tests directed to this matter I have come to the conclusion that *while "fixation-contraction" can be demonstrated in a fair number of cases it is neither universal in the musculature nor by any means so pronounced* as Foerster would have it. In various typical cases of Parkinsonism I have failed to satisfy myself of its presence except in *minor* degree, and not seldom, indeed, is it negligible. A further conclusion is, that *it is no more than a manifestation of increased somatic proprioceptive tone and as such is not deserving of a special terminology.*

To investigate its occurrence a number of cases of well-marked *unilateral Parkinsonism* were selected and the condition on one side compared minutely with that of the other. The tibialis phenomenon was made the subject of special examination; another *convenient test* is to approximate the origin and insertion of the deltoid by passive lifting and supporting of the arm in the vertical position. Many other muscles, however, were also utilised. To convince oneself of the presence or absence of "fixation-contraction" the muscle in question was examined with the eye, was palpated with the finger (an assistant performing the passive movement), and, if it so happened that the action of gravity came into play when *the limb segment* was deprived of this passive support, the time taken to fall was estimated on the two sides respectively. Speaking generally, *no* pronounced or *persistent tonic* contraction in the approximated state was observed in any particular muscle—at the most, as already stated, only moderate or minor degrees of the *condition could be found.*

In no case have I or my assistants been convinced of the development by this method of a muscular state that can fairly be represented *as belonging* to the category of *catatonia (or* catalepsy, as both Jakob and Foerster term it, though use of the word in this connexion should be avoided). If the *foot* takes longer to drop through gravity on the affected than on the *normal side, if* as the arm falls from the vertical an evident "catch" is demonstrable just as the movement begins, this is no more than what is to be expected in a hypertonic muscle or muscle group, *and cannot* be thought to constitute *per se* a pathognomonic sign of extrapyramidal rigidity. There is truth in the argument of Mayer, that in some instances at least "fixation-contraction" is *nothing else than a stretching* contraction, such as has been already illustrated in the previous section. Even in well-marked examples of Parkinsonian rigidity, when passive *shortening of a* given muscle (as when the *flexed lower* extremity is extended to an angle, say, of 135° at the knee, the quadriceps being thereby shortened) is made, but the extreme position not attained, it is not my experience that the limb is thus held immobile by the development of a "fixation-contraction," or, even so, I cannot assent to the interpretation put on this by the observers mentioned. At the most, it is identical with a phase of the "lengthening and shortening reaction," a property of proprioceptive tone, and merits neither separate description nor explanation.

When, therefore, Jakob maintains that the phenomenon of "fixation-contraction" is responsible for "cataleptic" (catatonic) symptoms in Parkinsonism, for the development of contractures, for adiadochokinesis and the various "pulsions," the impeding of voluntary movement, the slowing of movement at its commencement, and the interruption of movements in series, all this in my view is tantamount merely to the fact that hypertonia (exaggerated reflex contraction) of the musculature interferes with the prosecution of normal muscular action.

THE LORE OF THE ANTAGONISTS, AND THEIR RÔLE IN DISEASE OF THE CORPUS STRIATUM.

I have left to the end of my necessarily somewhat long analysis of movement and tone the *quæstio vexata* of the nature of the part played by the antagonists in normal "voluntary" motion, and the correlative problem, whether in the motor symptoms of striatal affections any, and if so, which, are to be ascribed to disordered function of this component of movement.

In his Croonian lectures before this College (1903) the late Dr. Charles Beevor summarised the two divergent theories then in vogue as to antagonistic function: (1) According to Winslow (1750) and Duchenne (1867) the antagonists take part in all "voluntary" movements, their function being to moderate (check, control) the contraction of the prime movers or protagonists, for the sake of precision of movement. Demeny (1890) drew a distinction between resisted and non-resisted "voluntary" movements; in the case of the former, the antagonists relax; in the case of the latter, they are in action during the primary movement. (2) According to Sherrington, when contraction of the principal muscles taking part in a given movement is effected by cortical (electrical) stimulation there is both relaxation and inhibition of the tone of the antagonists of this movement. Even with minimal excitation of the motor cortex relaxation of the antagonists is still obtained. From his own clinical observations Beevor concluded that in strong movements against resistance the antagonists are always relaxed, and that in unopposed movements (gravity being excluded) relaxation is the rule. In support of this second conclusion my old chief instanced the fact of the absence of demonstrable contraction in the left (say) sternomastoid when the right sternomastoid is the prime mover, as in rotation of the head to the left. Repeating this test a number of times, I am able to confirm its accuracy, but we must remember that the left posterior rotators come into action in head rotation to the left *before* the right sternomastoid does—the latter not contracting till the head is well past the mid-line—that they therefore are prime movers in the act, and, accordingly, the antagonists to the movement are constituted by the right posterior rotators. If these are examined it will, I think, be found that they do not absolutely relax, but decontract in moderating the desired movement. It is doubtful, therefore, whether the sternomastoid illustration really justifies the deduction drawn by Beevor from it.

Needless confusion has arisen from failure to appreciate the exact meaning of "relaxation" of an antagonistic group when protagonists contract. This has been taken erroneously to imply constant, complete, and immediate relaxation, whereas the words of Sherrington are that the contraction of the one muscle rises as that of the other falls, and the rise of the one keeps sufficiently close step with the fall of the other. No primary conflict between the two theories exists, nor any insurmountable difference. Amplification, however, is desirable.

To get a clear idea of antagonistic function we must bear in mind the *essential variability of antagonistic rôles*. Any stereotyped notion of antagonists being somehow "opponents" is fatal to clear thinking. We may speak of the antagonists *in* a movement, but never *to* a movement. "Opposite" muscles are not *ipso facto* "opposing" muscles. Their function ranges from (1) active coöperation in a movement, so that it is indistinguishable from that of prime movers, (2) through harmonious decontraction, as in ordinary displacements of a joint, to (3) a relaxation as quick and complete as possible, when the prime movers are acting powerfully against resistance. In illustration of this latter function, let the observer extend his arm laterally to a point well above the horizontal level at the shoulder, the deltoid being in full protagonistic action. In this position let him place his hand on a convenient shelf or ledge and make strong downward movement of the extended arm against this resistance. No displacement is possible, but the deltoid, now the antagonist in the required movement, immediately and with remarkable completeness can be felt under the fingers to soften and relax. There is here no moderating function, since no displacement as a fact occurs. In illustration of the first-mentioned function, I may cite the "straight left" of the boxer, when, accurately speaking, protagonists and antagonists as usually understood are in active cooperation, there being again no joint displacement. Beevor's illustration of the conversion of the leg similarly into a rigid muscular pillar, as when skating on the "outside edge," is equally apposite.

As I conceive it, recognition of this variability in antagonistic action will explain what might otherwise appear mutually discordant phenomena. At any moment in the course of a voluntary movement the character of antagonistic coöperation may alter according to requirements; it may change from decontraction to synergic coöperation, or again to relaxation, as the prime movers pass from kinetic to static action, or encounter resistance, and so forth. Differing modalities of function in the antagonists correspond to variations in protagonistic action. No haphazard or indiscriminate correlation, however, exists between the two; on the contrary, all is in strict physiological harmony.

As is known, the relationship of agonist contraction with simultaneous antagonist decontraction in ordinary joint displacements was described by Sherrington as "reciprocal innervation," and this "law" has received unqualified acceptance ever since its enunciation. That any conflict of the "pull-devil-pull-baker" kind should exist as between, say, flexor and extensor groups during displacement at the elbow in the direction, say, of flexion, is, in fact, both clinically and physiologically, unthinkable. He also, however, has demonstrated the occurrence and explained the nature of what he calls "double reciprocal innervation," a physiological state in which the centres for both prime movers and antagonists may discharge together, though unequally. In this way Sherrington covers the cases both of increase of protagonistic contraction with diminution of antagonistic contraction, and of simultaneous contraction (or, of reversion into rest) of the two groups.

These lectures were nearly completed when a communication by Prof. Frederick Tilney and Dr. Frank H. Pike was published in America. These investigators, experimenting on cats and monkeys, say, in so many words, that "under normal conditions we have not observed the contraction-relaxation phenomenon which is generally known as Sherrington's 'reciprocal innervation.' This phenomenon, although also observed by Beaunis in rare instances, was deemed by him both exceptional and inexplicable." Their view is that in all voluntary movements synchronous "co-contraction" takes place in the antagonists; they speak of "synergic units" composed of both flexors and extensors, and so on, and in each "synergic unit" there is a "dominant" element (the prime movers) and a "check" element (the antagonists). During action each exhibits "a proportional mutual increment of tension," which in the case of the former is "uniformly greater" than in the case of the latter. There are also differences in the "times" when this increment of tension comes into action in the two respectively. I cannot in this place attempt any examination of their researches as these may bear on the problem before us, but I may allow myself one comment. These workers do not appear, on the clinical side, to have envisaged all the possibilities of antagonistic action, since no investigation, seemingly, either of "voluntary" movement against strong resistance, or of antagonistic coöperation, has been made. The experimental side of their research undoubtedly seems to conflict on the face of it with Sherringtonian conceptions based also on experimental methods, but all that need now be said is that I do not think there is so complete a disparity as might at first appear between some (at least) of their findings, and the usual clinical interpretation of the rôles played by muscular components in individual "voluntary" movements. With the strictures passed by Tilney and Pike, Golla and Hettwer, and others, on the imperfections of ordinary clinical methods, I am in partial agreement, but I do not admit that comparisons between cases all of which are submitted to the *same* technique of examination are illegitimate or uninformative, or that clinical investigation is to be renounced in favour of electromyographic technique. Indeed, Tilney and Pike enter a word of caution against basing conclusions solely on records obtained in this way.

Relying, then, on well-tried clinical procedures and their application in the clinical study of striatal disease, *my conclusion is that in these affections the general laws of antagonistic action, as above illustrated, hold good.* From the records of Parkinsonian cases reproduced in Figs. 15, 16, and 18, contraction and decontraction can be demonstrated just as in normal individuals. No departure from normal states of diagnostic significance has been discovered. No "defective inhibition of antagonists," that is, no marked retardation, or failure, in making a particular movement on request through inability to relax the existing tension in an antagonistic muscle, has been noted, still less any instance of the antagonists coming into action *before* the prime movers, as we shall see occurs in other pathological conditions to receive attention. The Parkinsonian can employ his antagonists in coöperation, and, conversely, they can be shown to slacken when the occasion demands it, according to normal physiological precedent.

I find, of course, as has been already outlined, an impediment to quick alternating movements of a limb-segment in the existing hypertonia of both of two opposite groups. It must be obvious even to superficial observation that the fingers cannot be separated ("spread") with facility or quickness by *one* set of interossei if the reflex tonic contraction (hypertonia) of the opposite set cannot be inhibited with facility either. For while "volition" *adds* a contractile element to a muscle already in "involuntary" contraction, in the sense that the two blend, its action in the antagonistic component, also in "involuntary" contraction, should be to allow the latter to elongate and yet to maintain in elongation a moderating influence requisite for the particular end to be served. Admitting antagonistic activity in joint displacement, and not a mere passive or mechanical stretching of a relaxed muscle, the truth remains that this activity of innervation, this "increment of tension," is occurring in a muscle that is in fact *lengthening* itself, and the question is to explain the simultaneous activity of contracting and elongating elements. Only by inhibition, as I conceive it, of a *shortening* contractile process (such as takes place in the prime movers) can a muscle actually elongate while maintaining contractile tension; that is to say, the process in the antagonists cannot be physiologically *identical* with that in the protagonists. When a muscle is hypertonic its fibres are in a condition of greater (reflex) contraction, more tension, than in a normal muscle. If it happens to be *pro tem* an antagonist, then decontraction starts as it were behind scratch, and is adversely handicapped from the outset. Avoiding the language of metaphor, I say that more decontraction has to be effected in the antagonist (by a process of what I can only regard as inhibition) before the muscle begins to elongate, than is requisite in a normal antagonist. Hence the hindrance already alluded to, an impediment traceable through all Parkinsonian action in greater or lesser degree, and one to which many of the clinical phenomena here illustrated are in part at least attributable. Hence, in part, also, the "effort" of which the Parkinsonian patient is for ever complaining. The amount of innervation required for everyday movements, familiar to him by years of experience, turns out to be insufficient for the desired purpose; and he utters the simple confession, "it is easier not to make the movements."

An important and significant corollary arises from the conclusion to which this clinical study of striatal cases has led. Having found no abrogation of agonist-antagonist activities, no material departure from normal physiological laws except in so far as existing hypertonia causes a drag on rapidity and a reduction of facility, I am led to the decision that *the normal combining of protagonist, synergic, and antagonist muscular units in a single "voluntary" movement cannot be regarded as a function of the corpus striatum.* I need not at this point enter on a discussion as to the physiological level at which this combination takes place, since it will be dealt with subsequently. Suffice it to say that since the lesions of the cases under review are in all probability destructive or degenerative processes in the corpus striatum and its efferent systems, and since, as I have just pointed out, muscular components are in normal (if sometimes hampered) action as required, the mechanisms underlying their action are definitely non-striatal. Statements such as that of Lewy, therefore, that "the slackening of the antagonists during contraction of the agonists is dependent on the corpus striatum," are without either clinical or physiological foundation.

INVOLUNTARY MOVEMENTS.

Hitherto we have been concerned with an examination of two symptom-groups in the striatal triad—viz., those relating to the "voluntary" motor system, and those of muscle tone. Attention must now be directed to the question of so-called "involuntary movements."

In order to keep our study within appropriate limits I shall deal mainly with chorea, athetosis, and tremor. At the outset the caution must be repeated, that discussion of these symptoms in the present setting is not to be taken inferentially as implying for them a striatal origin. Further, the reader may with advantage recall the general comments made in my first lecture on the subject of "voluntary" movements and on the lack of precision in the meaning of the term.

The difficulties surrounding the problem may be set out as follows: (1) the classification and differentiation of the various kinds of "involuntary" movement have not been satisfactorily determined; (2) in a given case more than one type may make its appearance; (3) the movements are in many instances complicated by alterations in muscle tone, and their dissociation, however desirable for the purpose of study, is often far from easy; (4) lesions in different parts of the nervous system have at one or other time apparently been responsible for similar types of pathological movement; (5) conversely, lesions approximately in the same area have seemingly given rise to different varieties of movement; (6) the pathological findings in a particular case may be open to diversity of interpretation; (7) the evidence furnished by experimental methods has unquestionably been in some cases negative, in others conflicting.

Preliminary Considerations.

Before proceeding to clinical analysis, we must clear the ground by one or two preliminary considerations of basal significance, neglect of which still continues to be a source of confusion.

(1) It seems almost a platitude to point out that the phenomena to be dealt with are "positive" symptoms; they are over-mobile conditions; being movements, they cannot possibly be *caused* by impairment or destruction of movement-producing mechanisms—only paralysis, or absence of movement can thus result. Involuntary movements must be set down to *activity*, not to paralysis, of some or other motor mechanism, which must be in a physiological, not a pathological state. In every case of involuntary movement the phenomena occur during the action of *healthy* nervous arrangements, and constitute, as Hughlings Jackson insisted, a problem in physiology; they represent "physiology in difficulties." It is the more imperative to make this cardinal principle clear because it has been persistently ignored or minimised by many workers, especially in continental schools. To assign tremor and choreo-athetosis to destructive lesions of the corpus striatum is not only impossible, but ridiculous; a "hole" in the corpus striatum—for that is what outfall of parenchymatous cell-fibre systems means—cannot cause any movement whatsoever. Involuntary movements are the derivative of living mechanisms, and *our problem, therefore, is not what mechanisms are paralysed, but what mechanisms are active.*

(2) As an obvious corollary, if after the development of tremor, chorea, or athetosis a destructive lesion leads to cessation of the involuntary movement, then that lesion must be so situated as to interrupt the neural mechanism that has been producing the movement. Hence the special significance of all cases in which this class of movement has permanently ceased after a destructive lesion of one kind or another. Cases of this sort, it so happens, are rare, a fact which renders their careful investigation and recording the more desirable.

(3) A third consideration bears on the question whether the symptoms are produced by irritation, or are of the nature of release-phenomena. English neurology, following the lead of Hughlings Jackson, sees many objections to the idea of the production of year-long involuntary motor activity by irritation; yet the doctrine that excessive movement is thus caused still has adherents (Bing, for instance, still describes chorea and athetosis as "Reizsymptome," arising "when a capsular hæmorrhage implicates the neighbouring basal ganglia"). To determine the exact part played by irritation in the mechanics of symptom-production is no doubt difficult; of the precise nature of the process whereby cell activity passes from a static to a kinetic stage, we are still in complete ignorance. With some show of reason, therefore, it might be held we cannot prove that the liberation of stored-up energy is *not* due to some form of stimulation or "irritation"; even with withdrawal of inhibition some stimulus might still be postulated to initiate the discharge. The argument must be based accordingly on larger grounds.

(*a*) The duration of some of the cases of involuntary movement we meet with clinically puts "irritating lesions" out of court. That "irritation" should last practically a lifetime, as in some instances of Huntington's chorea, is scarcely conceivable, aside from the fact that we are equally at a loss to figure to the mind what sort of "irritation" might thus exist and continue indefinitely. It is equally difficult to imagine "irritation" of nerve-cells giving rise to the chronic tremor of paralysis agitans, or to the athetosis of an infantile cerebral hemiplegic, which may continue without ceasing for a quarter of a century or more.

(*b*) As long ago as 1876 Jackson said, "in some cases it seems to me to be evident that contemporaneously with the loss of function of a centre there is a rise in activity of the next lower centre." This is true not merely of diseased but also of healthy states. The activities of lower centres exhibit themselves freely in the absence of control from higher centres; conversely, the latter may compel the former to suspend their duties temporarily, as is readily exemplified by the action of "volition" on the respiratory mechanism. A sentence of Hughlings Jackson's, of which so far as I am aware no particular notice has hitherto been taken, seems to me to contain a truth of much significance (to which further allusion may be made); the centres of the lower physiological levels "are considerably independent of the directive influence of the higher levels, although much under their negative (inhibitory) influence." By reference to a physiological hierarchy of this kind the phenomena of involuntary movement can be more satisfactorily explained than by any process of "irritation."

(4) An integral part of the problem before us bears on the clinical distinctions between the different kinds of movement. If, as we shall see is the case, fundamental clinical differences can be established between the types—for example, between tremor and choreo-athetosis—then the probability of their being mediated by equally different physiological mechanisms becomes a practical certainty. That the same mechanism should be at one time responsible for athetosis, at another for tremor, is unthinkable. The import of this contention will become more obvious as we proceed.

CHOREA.

In reality a symptom, chorea is the name given to more than one disease. Sydenham's chorea is ætiologically distinct from Huntington's chorea; symptomatological chorea, on the other hand, is an episodic syndrome arising in the course of or as a sequel to encephalitis, cerebral vascular disease, tumours, and so on. In the two former, and indeed, unless they are exceptional, in the latter group also, the lesions underlying the clinical symptoms are characterised by diffuseness and are *ipso facto* valueless for the drawing of exact (localising) deductions therefrom; only in the case of quite small and circumscribed vascular lesions or tumours is it at all practicable to associate the choreic symptom with the pathological finding. Again, in the choreas that bear the names of Sydenham and Huntington, symptoms of a different class are frequently in evidence. Instead, then, of endeavouring to localise choreic movements by resort to an uncertain and, for the above reasons, quite unsuitable pathology, I urge the importance of the reverse procedure; we shall learn more of the nature and localisation of chorea by a precise investigation of its clinical phenomena than in any other way.

Clinical Characters of Chorea.

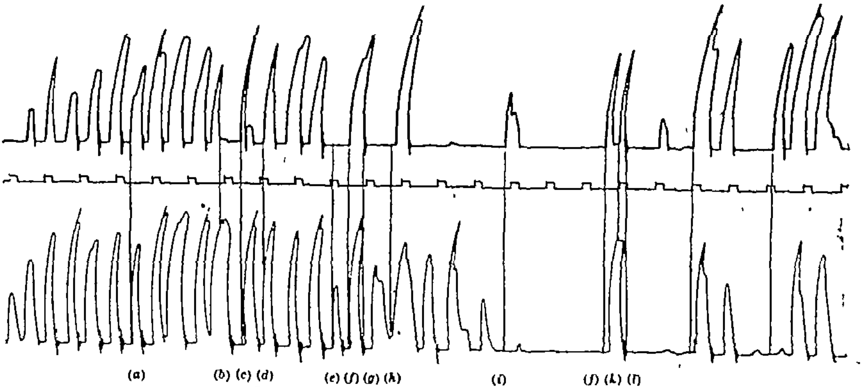
All of us can recognise a case of ordinarily well-marked chorea when we see it, difficult though the finding of an entirely satisfying definition of choreic movement may be. The following are some of the characters of this hyperkinesis :—

(1) The spontaneous movements of chorea offer an intimate resemblance to those executed at the bidding of volition. I mean thereby that they appear to be as complex (on occasion), as coördinated, and as purposeful as those of a frankly "voluntary" kind. Of their occasional or frequent elaborateness no doubt can be entertained; as a general rule, the muscular components of the movements take their specific physiological shares in synergia and sequence (to this rule there are important exceptions, as we shall shortly see); and each fresh movement appears to be directed to an end—which is never attained. Choreic motility may be described with sufficient accuracy as subjectively purposeful but objectively purposeless (cf. the difference between the German "zweckgemäss" and "zweckmässig"); in appearance only are the movements purposive, but to

describe them as purposeless without the qualification just given would be rather misleading.

Many previous writers have emphasised this general resemblance to "voluntary" movements. Hughlings Jackson *(1873) said*, "*they are not mere spasms and cramps*; they are an aimless [i.e., objectively aimless] profusion of movements of considerable complexity, much nearer the purposive movements of health." Again (1875), "the nature of the movements in chorea (a profusion of real movements—smiles, frowns, and gesticulations) is strong evidence that the back into the mouth at the signal for release, is an example in point. The child shoots his arms out in front when asked to extend them; told to stand up, he rises from his chair with an almost *amusing smartness and promptness. Walking down* the ward and asked to turn round, he performs the *movement with an abruptness that almost unbalances* him. That one and the same clinical feature should characterise *both* "voluntary" and "involuntary" actions has an important bearing on localisation and pathogenesis, as we shall duly see.

FIG. 24.



Case of senile chorea. Upper tracing gives contractions of quadriceps and lower tracing of external group of hamstrings (R. leg). Simultaneous record.

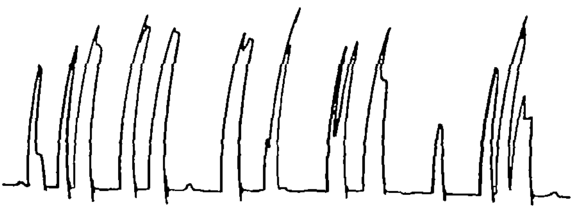
part diseased serves in highly special and complex coördinations, and thus that it is a part very high up in the nervous system." Cecil Wall, to whose excellent Bradshaw lecture on Chorea, delivered before this College in 1920, I wish to draw attention, also says: "I prefer the term 'spontaneous' to 'involuntary,' not because the latter is incorrect, but because the movements, though occurring independently of the will, are of the same type as movements executed *as the result of volition*."

(2) A further feature is their brevity and unsustained character, their abruptness, almost explosiveness. They rise and fall, wax and wane, with a peculiar rapidity. Occasionally, and by comparison rarely, a lingering decontraction obtains; the movement comes to an end as if with reluctance. Corroboration of the correctness of clinical observation in this respect is furnished by the electromyographic researches of Stanley Cobb, who has shown the essential similarity of the action-current curves for "voluntary" and for choreic movement, the difference residing in the shortness of the choreic contractions, as a rule, and in their lack of sustainment.

Now it is of especial significance that this feature of the spontaneous movements is *equally characteristic* of much of the patient's "voluntary" actions. As a fact, too, long after the "involuntary" gesticulations, as such, have vanished, the choreic child will often still exhibit noteworthy abruptness of "volitional" movement. The "choreic tongue," which flies

(3) A third point in respect of choreic movements is their separateness. However rapidly they follow each other, they do not, as a rule, blend into a continuum of motor activity, as is the case with athetosis. They remain discrete, and as long as they so remain, their coördination is comparatively undisturbed. To this rule, however, there are exceptions. *On occasion, one "involuntary" movement has not ceased before* its successor develops, and when coalescence of this kind occurs the clinical result is a medley of "spontaneous" muscular activity not to be distinguished in any essential particular from that of athetosis. I have had for long under my care an aggravated case of senile chorea (largely right-sided) in an old lady of over 80, from whom the records reproduced in Figs. 24, 25, and 26 have been obtained. With the slow-motion camera the *apparently* purposeful and coördinated nature of the never-ceasing large

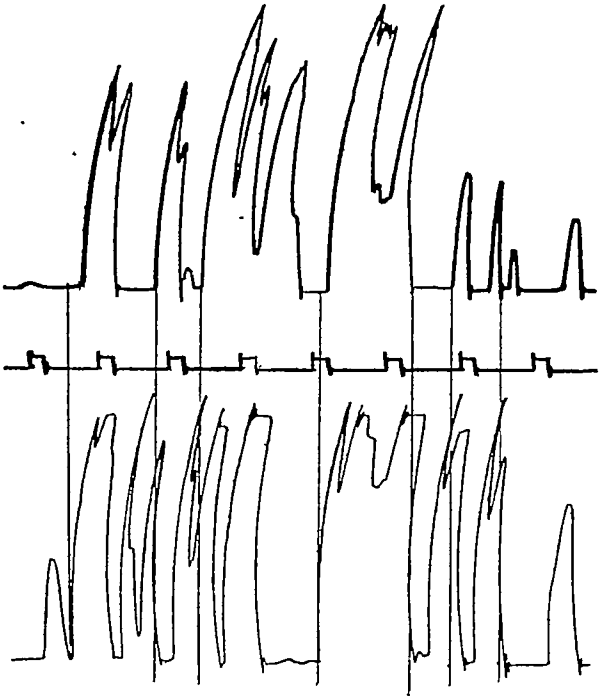
FIG. 25.



Same case as Fig. 24. Contractions of R. biceps.

and irregular movements is seen; if, however, the arm or the leg is so fixed as to minimise displacement, it is easy to convince oneself that movement follows movement in a confused, blended, and erratic fashion, and that the physiological laws governing the action and timing of the ordinary muscular components of coördinated movement are in complete abeyance. In a word, *Sherrington's law of reciprocal innervation no longer holds, disease having led to its negation.* For instance, attention is directed to Fig. 24, which gives a simultaneous tracing of the quadriceps (above) and the external group of hamstrings (below) of the right leg. Between (*a*) and (*b*) are five contractions of the extensors to four and a half contractions of the flexors, the opposite muscles contracting with practical simultaneity; the extensor contraction immediately after (*c*) is about twice as rapid as the flexor contraction after (*c*), though of practically the same extent; between (*f*) and (*g*) are simultaneous flexor and extensor innervations; between (*g*) and (*h*) the flexors alone contract, then at (*h*) both groups contract together, but flexor activity continues while extensor ceases; between (*j*) and (*l*) are two extensor innervations to one flexor, while at (*k*) the former commences at the very summit of existing contraction of the antagonists, yet the two end their decontraction together. Thus all sorts of pathological combinations of agonist-antagonist activity are exemplified in the record. Fig. 25 is from a tracing of the right biceps of the same case, and shows not only the complete irregularity in time and extent of the individual contractions of the muscle, but also (at (*a*)) how a second contraction supervenes on a first, before the latter has ceased. At (*b*), again, three contractions of the muscle follow on each other without a single break. In Fig. 26 are seen the contractions of the right biceps and triceps of the same case, and by comparing these as they occur between the various ordinates drawn on the record the dissolution of physiological "give-and-take" can at once be recognised. No clearer demonstration than that furnished by these and similar records of mine, of the *complete interruption of normal physiological reciprocal innervation during confluent choreic activity*, could be found.

FIG. 26.



Same case as Fig. 24. Simultaneous records of contractions of R. biceps (above) and R. triceps (below).

(4) This interference with the action of the normal components of a movement producing joint displacement is not, as a rule, to be discovered except in what I call "confluent chorea." Years ago, however, the late Dr. Beevor drew attention to the occasional occurrence in acute chorea of what he termed the "paradoxical contraction of the abdomen." In ordinary normal coördination the diaphragm descends during deep inspiration and at the same time the recti abdominis slacken; the upper part of the abdomen is seen to come forward, or, if the subject is recumbent, to rise, with descent of the viscera associated with the diaphragmatic contraction. Now sighing inspiratory movements are fairly frequent in severe choreas, and on occasion, with inspiration, the abdominal muscles can be clearly observed to contract paradoxically, rendering the upper abdomen concave instead of, as normally, convex. Here is a definite clinical instance of lack of harmony between the constituent muscular units of a choreic movement, and of abrogation of physiological sequence.

I have studied several cases of Huntington's chorea from the standpoint of normal muscular action, using for the purpose the scheme previously described. Interruption of the normal interplay of constituent muscles is but rarely found, though when it occurs it is definite enough. For example, I have seen dissociation of the normal elevation of the eyebrows with upward deviation of the eyes, also of head extension in depression of the lower jaw against resistance. With the patient recumbent, I have seen disturbance of the normal sequence of sternomastoid, recti abdominis, and rectus femoris action in the movement of rising to a sitting position.

Both in "involuntary" and in "voluntary" movement, therefore, in the case of chorea, proof of the not infrequent interruption of physiological law in the performance of movements requiring harmonious coördination of prime movers, synergists, and antagonists, as well as in those which I have called movements of sequence, has been obtained.

The "Choreic Hand" and its Relation to "Physiological Shift."

(5) The earliest reference I have been able to find to the "choreic hand" (though not with this specific term applied to it) is in the volume by Francis Warner entitled "Physical Expression" (1885). It is constituted by flexion at the wrist and hyperextension at the metacarpo-phalangeal joints, the phalanges being straight or moderately over-extended (or very slightly flexed), the fingers usually rather separated, and the thumb rather over-extended and abducted. Warner found this attitude (to which he gave the name of the "nervous hand") *inter alios* among "those convalescent from chorea," and he also stated: "It is also often seen on one side only, especially in children convalescent from hemichorea." I have, myself, for years given attention to the choreic hand and have remarked its presence in an extremely high percentage of cases; it may persist, like the abruptness of "voluntary" movement already alluded to, long after "spontaneous" choreic movement has ceased. Without exception it will be found to be more pronounced on the side (if there be such) on which the spontaneous movements are (or have been) the more frequent. Its occurrence, therefore, must be linked with the mechanism or mechanisms implicated in the mediation of these movements.

Now, while the posture of the choreic hand may be adopted momentarily in the course of a "spontaneous" choreic movement, this is undoubtedly somewhat rare; to demonstrate it most easily the patient is asked to extend his arms in front of him. The hands then assume the posture of wrist flexion and metacarpo-phalangeal extension, often in a strikingly exaggerated form. When a normal individual is requested to hold out his hands a difference is usually noticeable according as the movement is made energetically or gently; in the latter case *they are seen to fall into a posture of moderate* extension at the wrist with probably slight flexion of the fingers; in the former the fingers will be rather more extended, though the wrists will probably be extended, as before. The adoption of the choreic hand by the patient, however, is by no means merely an expression of the energetic abruptness of the "voluntary" movement, for it is readily obtained in numerous instances where the movement is not so characterised.

The choreic postural hand, as a moment's consideration shows, *is the exact reverse, the "corresponding opposite,"* of that posture of the hand which *is seen in everyone as the arms depend in rest by* the side, or, for that matter, in any easy resting position—viz., extension of the wrist and flexion of the fingers—the expression of activity of the normal synergic muscles for grasping. The extensors of the wrist are the normal synergists to the protagonistic long flexors of the fingers and their physiological association is intimate, constant, and incessant. Now, as anyone can at once discover for himself, it actually *requires a conscious effort to assume the choreic* attitude "voluntarily," and the more pronounced the attitude the more is he aware of strain and effort in making and maintaining it. One reason, doubtless, for this feeling resides in the infrequency, indeed, the rarity, of any "voluntary" movement or posture of this particular sort. Yet this is the precise posture effected by a disordered condition of the neural centres and mechanisms concerned. *That is to say, in the case of the choreic hand there is an* "involuntary" (for though occurring in the course of a "voluntary" movement it is certainly not assumed consciously by the patient) adoption of a posture the exact opposite of that constantly seen in normal persons in a resting state, and of that ordinarily found in the hand when the arm is held out; in other words, *a "physiological shift" occurs from one posture to its corresponding opposite.* When the sole of the foot is stimulated in the normal individual a movement of plantar flexion takes place; in states of pathological function of the pyramidal system a similar cutaneous stimulus, applied in a similar place, gives rise to a movement of plantar extension—there is a physiological "shift" from one movement to its opposite. This provides us with an indirect but none the less valuable analogy by which to endeavour to explain the choreic phenomenon, and one of wide applicability, though I cannot enlarge on it further at present. The demonstration of this physiological "shift" in the case of chorea can fairly be taken to argue a condition of abnormal function of the corticospinal system, though with the immediate proviso that this abnormal state need neither be of a structural sort nor have its ultimate origin on the motor or effector side.

The Pronator Sign.

(6) Other "little signs" in chorea are indicative of a condition of disordered corticospinal function. In unilateral instances Babinski's "rising sign," described by him for cases of hemiplegia, is often obtainable on the affected side. Occasionally an extensor plantar response is found in chorea; I have seen it more than once but do not stress the point unduly. Much more frequent is the so-called "pronator sign," the arm assuming the same position of pronation or semi-pronation at the elbow as is seen in hemiplegia. When the choreic holds *out* his arms the thumbs are often seen to "dip" more than normally, indicative of some forearm pronation; a better way is to have the patient *extend* his arms above his head, when the palms are observed to turn outwards, sometimes to a pronounced degree, thus revealing an "involuntary" over-pronation at the elbow. In a paper on decerebrate rigidity in man allusion has already been made to some of these phenomena and the suggestion put forward that choreic postures—the choreic hand, the pronator sign—are *pro tanto* indicative of the partial release from "voluntary" control of mechanisms that are *wholly released in complete decerebrate rigidity.* The suggestion has been quite misunderstood in certain quarters, but from what has been outlined above it will be seen to indicate simply the fact that certain analogies obtain between the results of release of function in chorea and of release in disorder, *inter alia*, of the corticospinal system. In a recent communication I have argued from clinical data that the results of complete single release (hemiplegia, paraplegia) are not identical with those of complete double release (decerebrate rigidity—cortical efferent systems plus striatal efferent systems.)

"Paralytic" Chorea.

As further evidence of the point at present under consideration, reference may be made to cases of chorea signalised rather by weakness and inactivity of a limb or limbs than by "spontaneous" movements of the same. The complaint in these cases is always one of "losing the use" of the limb. Objects are dropped from the hand; the arm hangs practically motionless; weakness of grasp is often pronounced. *Such cases are by no means rare, and were described* originally as "paralytic chorea" by Sir William Gowers in 1880, and as chorea mollis by Samuel West. In any ordinary case, too, some muscular weakness can usually be discovered. In my experience of flaccid chorea, the greater the weakness the fewer are the spontaneous movements; with return of power the latter may for a time increase; hence the apparent paradox that the child *seems to the parents to be "getting worse" when* as a fact improvement has set in.

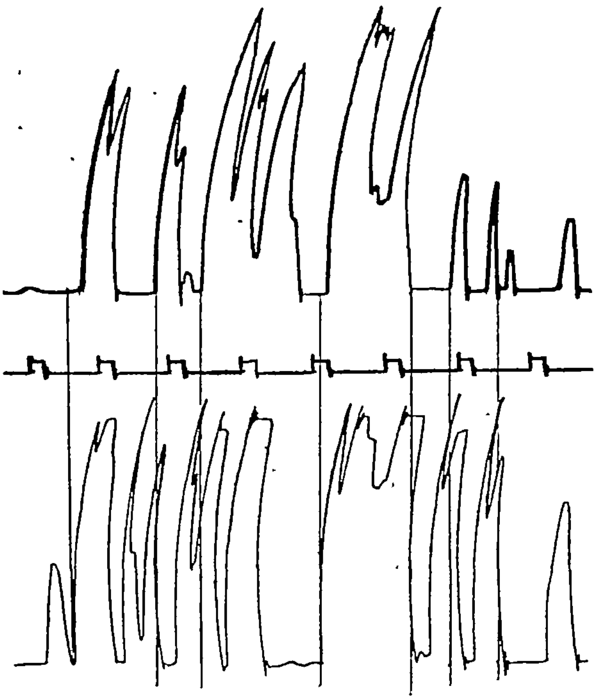
The significance of such cases will be better understood if we bear in mind the important principle that "weakness" or hypokinesis and "involuntary movements" or hyperkinesis are but different aspects of activity of the same mechanisms; in one case there is underaction, in the other, overaction, of motor function. Hypokinetic chorea is as it were the obverse of hyperkinetic chorea; and we should not, therefore, seek a quite *different mechanism for each,* but rather expect to find that in the case of the latter the efferent corticospinal system is less disordered than in the former.

(7) The general state of muscle tone in chorea is of significance in relation to problems of localisation and pathogenesis. Commonly speaking, choreic musculature is definitely hypotonic, both as regards the usual and the "paralytic" type, and allows of greater extent of passive movement than in normal persons of the choreic age, say 7 to 15. Further, in numerous instances of *Sydenham's chorea* the knee-jerk exhibits that pendular character which is found in hypotonic cases of cerebellar origin. Though the *hamstrings are passively stretched* by the shortening reaction of the quadriceps their tone is relatively so low that a "stretching-contraction" does not take place; the leg, therefore, swings like a pendulum. The knee-jerk differs not in kind but in degree from the cerebellar knee-jerk, which exhibits the phenomenon often in a more striking fashion. (A cinematographic film of the pendular knee-jerk in chorea was shown.)

(8) One other clinical consideration remains before we seek to draw conclusions as to pathogenesis from our clinical data. Among the *spontaneous* movements of chorea are to be found many involving the muscles of facial expression; across the choreic's face flits an exaggerated smile, to be followed in a moment by an expression of preternatural gravity. Frowns, smiles, sighs, chase each other unendingly; *when the choreic* tongue flies back at a word into the mouth the face is often liable just then to be disturbed by a series of expressional activities. These transient emotional or mimic displays, however, are essentially *movements; one does not, as a rule,* observe individual muscular twitches, myoclonic contractions of individual muscles, never any localised muscular caricaturing as in facial spasm. If unilateral grimacing occurs, it offers the same features as facial tic. Almost invariably those

and irregular movements is seen; if, however, the arm or the leg is so fixed as to minimise displacement, it is easy to convince oneself that movement follows movement in a confused, blended, and erratic fashion, and that the physiological laws governing the action and timing of the ordinary muscular components of coördinated movement are in complete abeyance. In a word, *Sherrington's law of reciprocal innervation no longer holds, disease having led to its negation.* For instance, attention is directed to Fig. 24, which gives a simultaneous tracing of the quadriceps (above) and the external group of hamstrings (below) of the right leg. Between (*a*) and (*b*) are five contractions of the extensors to four and a half contractions of the flexors, the opposite muscles contracting with practical simultaneity; the extensor contraction immediately after (*c*) is about twice as rapid as the flexor contraction after (*c*), though of practically the same extent; between (*f*) and (*g*) are simultaneous flexor and extensor innervations; between (*g*) and (*h*) the flexors alone contract, then at (*h*) both groups contract together, but flexor activity continues while extensor ceases; between (*j*) and (*l*) are two extensor innervations to one flexor, while at (*k*) the former commences at the very summit of existing contraction of the antagonists, yet the two end their decontraction together. Thus all sorts of pathological combinations of agonist-antagonist activity are exemplified in the record. Fig. 25 is from a tracing of the right biceps of the same case, and shows not only the complete irregularity in time and extent of the individual contractions of the muscle, but also (at (*a*)) how a second contraction supervenes on a first, before the latter has ceased. At (*b*), again, three contractions of the muscle follow on each other without a single break. In Fig. 26 are seen the contractions of the right biceps and triceps of the same case, and by comparing these as they occur between the various ordinates drawn on the record the dissolution of physiological "give-and-take" can at once be recognised. No clearer demonstration than that furnished by these and similar records of mine, of the *complete interruption of normal physiological reciprocal innervation during confluent choreic activity*, could be found.

FIG. 26.



Same case as Fig. 24. Simultaneous records of contractions of R. biceps (above) and R. triceps (below).

(4) This interference with the action of the normal components of a movement producing joint displacement is not, as a rule, to be discovered except in what I call "confluent chorea." Years ago, however, the late Dr. Beevor drew attention to the occasional occurrence in acute chorea of what he termed the "paradoxical contraction of the abdomen." In ordinary normal coördination the diaphragm descends during deep inspiration and at the same time the recti abdominis slacken; the upper part of the abdomen is seen to come forward, or, if the subject is recumbent, to rise, with descent of the viscera associated with the diaphragmatic contraction. Now sighing inspiratory movements are fairly frequent in severe choreas, and on occasion, with inspiration, the abdominal muscles can be clearly observed to contract paradoxically, rendering the upper abdomen concave instead of, as normally, convex. Here is a definite clinical instance of lack of harmony between the constituent muscular units of a choreic movement, and of abrogation of physiological sequence.

I have studied several cases of Huntington's chorea from the standpoint of normal muscular action, using for the purpose the scheme previously described. Interruption of the normal interplay of constituent muscles is but rarely found, though when it occurs it is definite enough. For example, I have seen dissociation of the normal elevation of the eyebrows with upward deviation of the eyes, also of head extension in depression of the lower jaw against resistance. With the patient recumbent, I have seen disturbance of the normal sequence of sternomastoid, recti abdominis, and rectus femoris action in the movement of rising to a sitting position.

Both in "involuntary" and in "voluntary" movement, therefore, in the case of chorea, proof of the not infrequent interruption of physiological law in the performance of movements requiring harmonious coördination of prime movers, synergists, and antagonists, as well as in those which I have called movements of sequence, has been obtained.

The "Choreic Hand" and its Relation to "Physiological Shift."

(5) The earliest reference I have been able to find to the "choreic hand" (though not with this specific term applied to it) is in the volume by Francis Warner entitled "Physical Expression" (1885). It is constituted by flexion at the wrist and hyperextension at the metacarpo-phalangeal joints, the phalanges being straight or moderately over-extended (or very slightly flexed), the fingers usually rather separated, and the thumb rather over-extended and abducted. Warner found this attitude (to which he gave the name of the "nervous hand") *inter alios* among "those convalescent from chorea," and he also stated: "It is also often seen on one side only, especially in children convalescent from hemichorea." I have, myself, for years given attention to the choreic hand and have remarked its presence in an extremely high percentage of cases; it may persist, like the abruptness of "voluntary" movement already alluded to, long after "spontaneous" choreic movement has ceased. Without exception it will be found to be more pronounced on the side (if there be such) on which the spontaneous movements are (or have been) the more frequent. Its occurrence, therefore, must be linked with the mechanism or mechanisms implicated in the mediation of these movements.

Now, while the posture of the choreic hand may be adopted momentarily in the course of a "spontaneous" choreic movement, this is undoubtedly somewhat rare; to demonstrate it most easily the patient is asked to extend his arms in front of him. The hands then assume the posture of wrist flexion and metacarpo-phalangeal extension, often in a strikingly exaggerated form. When a normal individual is requested to hold out his hands a difference is usually noticeable according as the movement is made energetically or gently; in the latter case they are seen to fall into a posture of moderate extension at the wrist with probably slight flexion of the fingers; in the former the fingers will be rather more extended, though the wrists will probably be extended, as before. The adoption of the choreic hand by the patient, however, is by no means merely an expression of the *energetic abruptness of the* "voluntary" movement, for it is readily obtained in numerous instances where the movement is not so *characterised.*

The choreic postural hand, as a moment's consideration shows, is the exact reverse, the "corresponding opposite," of that posture of the hand which is seen in everyone as the arms depend in rest by the side, or, for that matter, in any easy resting position—viz., extension of the wrist and flexion of the fingers—the expression of activity of the normal *synergic muscles for grasping. The extensors of the* wrist are the normal synergists to the protagonistic long flexors of the fingers and their physiological association is intimate, constant, and incessant. Now, as anyone can at once discover for himself, it actually requires *a conscious effort to assume the choreic* attitude "voluntarily," and the more pronounced the attitude the more is he aware of strain and effort in making and maintaining it. One reason, doubtless, for this feeling resides in the infrequency, indeed, the rarity, of any "voluntary" movement or posture *of this particular sort.* Yet *this is* the precise posture effected by a disordered condition of the neural centres and mechanisms concerned. That is to say, in the case of the choreic hand there is an "involuntary" (for though occurring in the course of a "voluntary" movement it is certainly not assumed consciously by the patient) adoption of a posture the exact opposite of that constantly seen *in normal* persons in a resting state, and of that ordinarily found in the hand when the arm is held out; in other words, *a "physiological shift" occurs from one posture to its corresponding opposite.* When the sole of the foot is stimulated in the normal individual a movement of plantar flexion takes place; in states of pathological function of the pyramidal system a similar cutaneous *stimulus, applied in a similar place*, gives rise to a movement of plantar extension—there is a physiological "shift" from one movement to its opposite. This provides us with an indirect but none the less valuable analogy by which to endeavour to explain the choreic phenomenon, and *one of wide* applicability, though I cannot enlarge on it further at present. The demonstration of this physiological "shift" in the *case of chorea* can fairly be taken to argue a condition of abnormal function of the corticospinal system, though with the immediate proviso that this abnormal state need *neither* be of a structural sort nor have its ultimate origin on the motor or effector side.

The Pronator Sign.

(6) Other "little signs" in chorea are indicative of a condition of disordered corticospinal function. In unilateral instances Babinski's "rising sign," described *by him for cases* of hemiplegia, is often obtainable on the affected side. Occasionally an extensor plantar response is found in chorea; I have seen it more than once but do not stress the point unduly. Much more frequent is the so-called "pronator sign," the arm *assuming* the same position of pronation or semi-pronation at the elbow as is seen in hemiplegia. When the choreic holds *out* his arms the thumbs are often seen to "dip" more than normally, indicative of some forearm pronation; a better way is to have the patient extend his arms above his head, when the palms are observed to turn outwards, sometimes to a pronounced degree, thus revealing an "involuntary" *over*-pronation at the elbow. In a paper on decerebrate rigidity in man allusion has already been made to some of these phenomena and the suggestion put forward that choreic postures—the choreic hand, the pronator sign—are *pro tanto* indicative of the partial release from "voluntary" control of mechanisms that are wholly released in complete decerebrate rigidity. The suggestion has been quite misunderstood in certain quarters, but from what has been outlined above it will be seen to indicate simply the fact that certain analogies obtain between the results of release of function in chorea and of release in disorder, *inter alia*, of the corticospinal system. In a recent communication I have argued from clinical data that the results of complete single release (hemiplegia, paraplegia) are not identical with *those of complete* double release (decerebrate rigidity—cortical efferent systems plus striatal efferent systems.)

"*Paralytic*" *Chorea.*

As further evidence of the point at present under consideration, reference may be made to cases of chorea signalised rather by weakness and inactivity *of a limb or limbs than by "spontaneous"* movements of the same. The complaint in these cases is always one of "losing the use" of the limb. Objects are dropped from the hand; the arm hangs practically motionless; weakness of grasp is often pronounced. Such cases are by *no means rare, and were described* originally as "paralytic chorea" by Sir William Gowers in 1880, and as chorea mollis by Samuel West. In any ordinary case, too, some muscular weakness can usually be discovered. In my experience of flaccid chorea, the greater the weakness the *fewer* are the *spontaneous movements*; with return of power the latter may *for a time* increase; hence the apparent paradox that the child seems to the parents to be "getting worse" when as a fact improvement has set in.

The significance of such cases will be better understood if we bear in mind the important principle that "weakness" or hypokinesis and "*involuntary movements*" or hyperkinesis are but different aspects of activity of the same mechanisms; in one case there is underaction, in the other, overaction, of motor function. *Hypokinetic chorea* is as it were the obverse of hyperkinetic chorea; and we should *not*, therefore, seek a quite *different* mechanism for each, but rather expect to find that in the case of the latter *the efferent corticospinal system* is less disordered than in the former.

(7) The general state of muscle tone in chorea is of significance in relation to problems of localisation and pathogenesis. Commonly speaking, choreic musculature is definitely hypotonic, *both as* regards the usual and the "paralytic" type, and allows of greater extent of passive movement than in normal persons of the choreic age, say 7 to 15. Further, in numerous instances of Sydenham's chorea the knee-jerk exhibits that pendular character which is *found* in hypotonic cases of cerebellar origin. Though the hamstrings are passively stretched by the shortening reaction of the *quadriceps their* tone is relatively so low that a "stretching-contraction" does not take place; the leg, therefore, swings like a pendulum. The knee-jerk differs not in kind but in degree from the cerebellar knee-jerk, which exhibits the phenomenon often in a more *striking fashion.* (A cinematographic film of the pendular knee-jerk in chorea was shown.)

(8) One other clinical consideration remains before we seek to *draw* conclusi*ons as* to pathogenesis from our clinical data. Among the spontaneous movements of chorea are to be found many involving the muscles of facial expression; across the choreic's face flits an exaggerated smile, *to be followed in a moment by an* expression of preternatural gravity. Frowns, smiles, sighs, chase each other unendingly; when the choreic tongue flies *back at a* word into the mouth the face is often liable just then to be disturbed by a series of expressional activities. These transient emotional or mimic displays, however, are essentially *movements*; one does not, as a rule, observe individual muscular twitches, myoclonic contractions of individual muscles, never any localised muscular caricaturing as in facial spasm. If unilateral grimacing occurs, it offers the same *features as facial tic. Almost invariably those*

movements are bilateral which in health are bilateral; dissociation occurs in lower facial movements but not in upper, consonant with normal physiological law. I have not observed unilateral contractures of the frontalis, for example. We must not imagine the fragments of emotional facial expression exhibited haphazardly by the choreic to correspond to any existing emotional state of the moment; rather are they to be regarded as a release of the efferent side of the mechanism for the expression of the emotions. In a previous communication evidence has been adduced suggesting a cortical (non-rolandic) site for the central representation of mimic expression, and if this hypothesis is worthy of credence we may suppose in chorea a double condition of release: (1) the "voluntary" motor system (corticospinal system) is usurped by "involuntary" movements; (2) a normally "involuntary" efferent motor system (that for the expression of the emotions) is the seat of movements not occasioned by normal sensory (emotional) stimuli, but by abnormal (choreic) stimuli. Previous allusion has been made to the possibility of such a double release.

Summary of Clinical Analysis of Choreic Symptoms.

Summarising this analysis of choreiform phenomena, we have noted the close resemblance of choreic movements to "voluntary" movements, the existence of "little signs" pointing to disturbance of corticospinal function, the occurrence both in "voluntary" and in "involuntary" choreic action of identical clinical characteristics; we have seen the connexion between "paralytic" and hyperkinetic chorea, and realised how these are but differing aspects of derangement of the same efferent mechanism; while the occurrence in confluent chorea (as I call it) of motor incoördination which clearly demonstrates the abrogation of the law of reciprocal innervation by disease has also been exemplified.

Now the argument from these clinical data which is here offered may be stated as follows: Complete paralysis, as in, say, anterior poliomyelitis, is never under any circumstances associated with the appearance of involuntary movements in the affected limbs; similarly, in the case of a recent, complete, flaccid hemiplegia no involuntary movement (post-hemiplegic chorea or athetosis) makes its appearance until there is clinical evidence of some return of power in the paralysed limb or limbs. Even in cases of severe chorea the corticospinal system is never "paralysed"; but where "paralytic chorea," so-called, is noted the spontaneous movements are at a minimum. It is difficult to resist the conclusion that *for the appearance of choreiform disorder relative integrity of the pyramidal or corticospinal tracts is essential.* The corollary is, that this integrity is not absolute, in view of (1) the presence of the choreic phenomena themselves, and (2) the above-mentioned signs or indications of slight concomitant corticospinal dysfunction. I repeat, however, with due emphasis, that *the derangement constituting chorea need not have its actual origin on the motor (effector) side of cerebral (cortical) mechanisms*

Further argument may conveniently be postponed till the clinical phenomena of athetosis have been subjected to analysis.

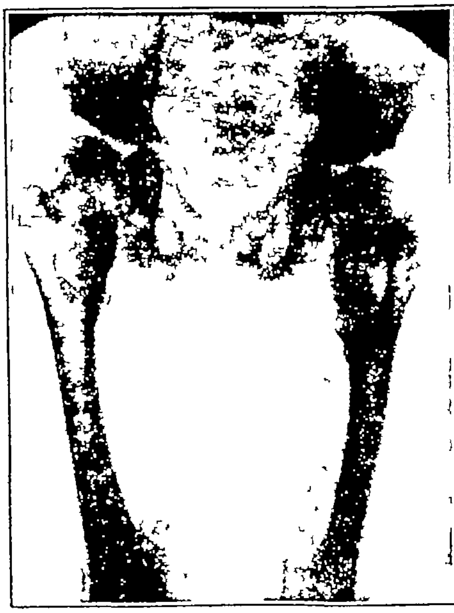
A CASE OF
HEREDITARY DEFORMING DYSCHONDROPLASIA.

BY A. G. ORD, F.R.C.S. EDIN.,
HON. ASSISTANT SURGEON, ROYAL PORTSMOUTH HOSPITAL.

THE following case of hereditary deforming dyschondroplasia seems worth recording, especially as there is available a genealogical tree of considerable interest.

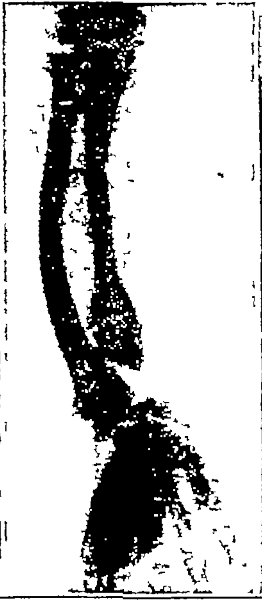
The patient, a boy of 14 years, was brought to my clinic by his mother with the story that "neighbours say that the boy has broken his arm." The boy was well developed for his age, but distinctly shorter than normal. He had a markedly sallow complexion, and was inclined to be "flabby." He was said to be "dull" intellectually. On examination his right forearm, when flexed on the elbow in the fully supinated position, with his arm at the side, was found to go across his body until his right hand rested on his left shoulder. No olecranon could be felt, and on further examination the distal end of the ulna was found to terminate in a bulbous extremity some 1 inch proximal to the wrist-joint. There was marked ulnar deflexion of the hand, but no fixed deformity in any

FIG. 1.



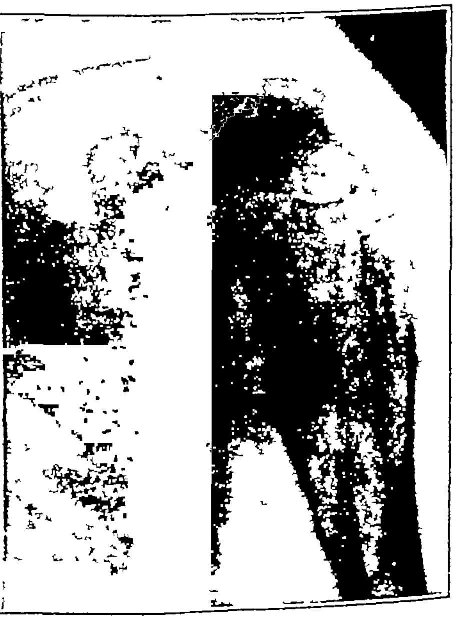
Hip joints and femora

FIG. 2



Right forearm.

FIG. 3.

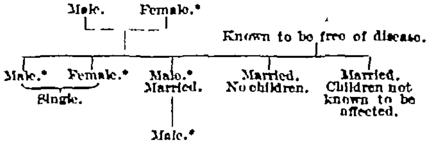


Left shoulder.

way. Both humeri at their proximal extremities appeared to be expanded, and although the left arm was less affected than the right, yet many irregular bosses could be felt. Both trochanters felt larger than normal, but were not raised above Nelaton's line. Around the knees and ankles many large and irregular bony prominences could be felt. The head, spine, and scapula appeared to be free of any abnormality. The accompanying X ray pictures show the outstanding features of the case. The only complaint was that stated above. But on carefully questioning the patient —originally a left-handed boy—he volunteered the information that he had difficulty in writing with his right hand which he had been made to use at school. Again, he stated that he could not play football very well because he could not run for long, presumably due to the accompanying coxa valga. The father also submitted himself to X ray examination, although he had no complaints excepting that he noticed his hips hurt him when he put his legs wide apart. The lesions found were of precisely similar nature, but their distribution was different, the chief bones affected being ilium—a boss on the ilium being almost contiguous with the greater trochanter on the left side—femora, tibiæ, and fibulæ and, to a lesser extent, the bones of the upper extremities. In every instance, however, the child's deformities were far greater, as demonstrated by X rays. This may be due to a worse affection or possibly to the fact that as adult life approaches some of the cartilage gets absorbed.

The family history is of interest, and although it is not quite complete yet the genealogical tree appended suggests strongly that the disease or abnormality is directly transmitted from a previously affected subject.

Genealogical Tree.



* = Known to be affected.

No satisfactory explanation has been offered for this remarkable condition, the most favoured theories being cartilaginous rests and thyroid or, at any rate, endocrine inefficiency. The latter is lent a little weight perhaps by these cases.

The boy was definitely a little below average in intelligence and had a peculiarly earthy complexion. The father also might possibly be indicted on the count of having said, with reference to the condition of his knees, that he thought "everyone was like this." These are, however, very slight indications and may easily be overstressed.

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A meeting was held in the School of Pathology, Trinity College, Dublin, on July 10th, Prof. J. T. Wigham in the chair.

W. M. Crofton (Dublin) urged that definite evidence of the ætiological relationship of microbes to disease could be obtained by the protective and curative results obtained with small doses of the organism. The fact, for example, that minute doses of "influenza" vaccine had a favourable effect on cases of lethargic encephalitis could not be neglected in considering the cause of that disease.—J. W. McLeod, G. M. Duthie, and H. V. Phelon (Leeds) discussed the significance of the production of alkali in cultures of the meningococcus and gonococcus.—J. W. Bigger (Dublin) had studied the hæmolysin of *Staphylococcus aureus* and found two bodies with a hæmolytic action, one heat-labile and acting on human and horse corpuscles, the other, relatively heat-resistant and produced much more slowly, acting on sheep and ox cells.—T. Dalling (London) showed that sheep could be satisfactorily protected in the field against braxy with a mixed vaccine of culture filtrates of *B. chauvei* with *Vibrion septique* toxin and antitoxin; laboratory experiments indicated that protection against blackleg could be obtained in the same way.—A. E. Boycott and C. Price-Jones (London) found that violent exercise determined illness and death in rats fed with cultures of Gaertner's bacillus though it had no obvious ill-effect on inoculated animals.—C. Price-Jones and N. D. Ball (London) described a chronic epidemic of Gaertner infection in a laboratory stock of rats; in about 15 months 19 deaths occurred in some 600 animals, and when the surviving animals were killed and examined signs of infection were found in 28 of 142. The organism was of low virulence and there was little parallelism between the occurrence of the bacilli in the spleen and of specific agglutinins in the blood.—S. C. Dyke (Wolverhampton) traced the rise and subsequent fall in the number of blood platelets after splenectomy in a case of acholuric jaundice; there was some eosinophilia, but the changes in the platelets had no apparent relation to the changes in the red corpuscles or leucocytes.—W. J. Wilson (Belfast) described a method of counting blood cells without a hæmocytometer by the use of a standard suspension of stained red corpuscles.—J. S. Dunn and Nora A. Lovett (Manchester) had studied the later stages of experimental oxalate nephritis in rabbits. Anatomically, there was atrophy of the convoluted tubules with condensation of the connective tissue in slight cases and some fibrosis in more severe examples; the glomeruli seemed hardly affected. The functional capacity of these kidneys was tested by putting the animals on a dry diet. This normally leads to a considerable decrease in volume of urine with a rise in the urea percentage and a concentration of urea from blood to urine of about 250 times. In the nephritic animals the kidneys were almost or quite unable to effect this concentration and the blood-urea rose to a dangerous extent when water was withheld.—J. S. Dunn (Manchester) described a case of unexpected death in an infant associated with multiple hæmorrhages in the parathyroids.—A. E. Boycott and C. Diver (London) drew attention to the occurrence of monsters and very high embryonic mortalities in certain strains of snails obtained in their breeding experiments, fatality being associated with uncertainty as to the direction of the spiral twist of the shell.—J. T. Wigham and E. C. Smith (Dublin) demonstrated a series of kidney tumours, W. J. Wilson (Belfast) a simple apparatus for plate cultures of anaerobes, B. W. Longhurst (Bath) a series of microphotographs taken with the Davon supermicroscope, E. E. Glynn (Liverpool) a gonorrhœal stricture of rectum and two large cutaneous horns, M. J. and C. Stewart (Leeds) a renal hypernephroma and a chondrosarcoma of tibia which had permeated veins, A. L. Taylor (Leeds) a primary actinomycosis of muscle and a very early anthrax pustule, W. G. Barnard (London) a series of human parathyroids showing the two types of cells, an angeioma of the parathyroid, and specimens showing squamous epithelium in the stalk of a normal pituitary and in a pituitary tumour.—G. S. Williamson and Innes H. Pearse (London) reviewed the functional changes in the thyroid in the light of Aschoff's conception of the reticulo-endothelial system.—T. Houston (Belfast) described experiments on the amœboid and phagocyte activity of leucocytes in blood and pus, and a new method of doing Arneth counts.

Reviews and Notices of Books.

THE MINISTRY OF HEALTH.

By Sir ARTHUR NEWSHOLME, K.C.B., M.D., F.R.C.P. The Whitehall Series. London: G. P. Putnam's Sons, Ltd. 1925. Pp. 265. 5*s*.

Sir Arthur Newsholme, who was Principal Medical Officer to the Local Government Board from 1908 to 1919, provides an interesting survey of public health work. Like the other volumes in the series, it is designed to meet the needs especially of Members of Parliament and civil servants. The first chapters deal with the early institution of public health work in connexion with the Poor-law and the formation and development of the Local Government Board, culminating in the creation of the Ministry of Health. Subsequent chapters describe the gradual growth of local public health work, and the author points out as an obstacle to efficient sanitary organisation the existence of the smaller units of administration. He believes that the formation of larger units with more comprehensive duties would help to remove a certain lack of local patriotism evidenced by the failure of rate-payers to vote at local elections. Responsible local authorities for health work are not always secured, and this, the author considers, makes it hard to balance central and local control, while he holds that a preliminary training or experience in local administration would increase the efficiency of the members of public services. In a chapter on the scope of public health work it is suggested that each medical practitioner might become a medical officer of health in the range of his own practice, acting, no doubt, under the principal officer, envisaged by the creation of large areas. We gather that, in the author's view, coördination locally is more important than coördination centrally, and that the greatest need is devolution on a large scale to county councils and county borough councils and a higher measure of trust in these bodies. The existence of the majority and minority reports of the Poor-law Commission issued in 1909 did not excuse, in Sir Arthur Newsholme's opinion, the inauguration of a national insurance against sickness which ignored existing official conditions and arrangements. Both of these reports at any rate agreed that the boards of guardians should be abolished and their duties transferred to county councils and county borough councils, and as a similar recommendation was made by the Maclean Committee in 1917, it is difficult to find reasons for further delay.

Large sections of public health work, including vital statistics and quarantine questions, are not dealt with in any detail, and from the author's preface it may be gathered that he found the story which had to be told too long and elaborate for the conditions of its telling. Much, however, may be learned from its pages.

THORACIC SURGERY.

Die Chirurgie der Brustorgane. Vol. II. By FERDINAND SAUERBRUCH. Berlin: Julius Springer. 1925. 258 gold marks (=£12 18*s*.).

THE second volume of Sauerbruch's monumental work on the surgery of the chest contains 1075 pages, 715 illustrations, many of them in colour, and weighs 6 lb. 12 oz. The first volume, which appeared five years ago, dealt with the anatomy and physiology of respiration, the general pathology of disease of the thoracic viscera, diagnosis by means of radiology and clinical methods, anæsthesia, pressure chambers, and the general technique of thoracic surgery and special forms of operations on the lung. The present volume shows the same breadth of outlook and attention to detail. It deals in succession with the surgery of the mediastinum, the heart and pericardium, the large blood-vessels, the thymus, the œsophagus, the diaphragm, and the pleura; and included in it is the second edition of the "Technik der Thoraxchirurgie," by Sauerbruch and Schumacher, which was issued by the same publisher in 1911. The two volumes embody painstaking pioneering work of the first order, and form the most important publication on thoracic surgery that has yet been made. The interest is not confined to the surgeon, for many aspects of thoracic disease have been considered, from secondary carcinoma of the breast involving the parietes, to tuberculosis and tumours of the lungs, animal parasites of the pleural cavity, and gunshot wounds. On each and every subject important help is given in diagnosis as well as operative technique. The bibliography extends to 110 pages. The book excels alike in composition, material, and production.

PRACTICAL CHIROPODY.

By E. G. V. RUNTING, a Founder and the first President of the Incorporated Society of Chiropodists. London: The Scientific Press. 1925. Pp. 164. 5*s*.

IT is many years since a treatise on chiropody has been published in England, and this book is a great advance on its predecessors. A full account is given of the treatment of corns, plantar warts, and affections of the nails, and a useful chapter follows on the pads and plasters which the skilful chiropodist applies after he has laid down his knife. The book is a clear indication that the modern chiropodist is taking his calling seriously, and is using scientific knowledge to improve his work. The pupil is warned not to go outside his sphere and always to order the client to consult a doctor in cases where there is any suspicion that the trouble arises from a constitutional rather than a local cause. In place of the word "corn" the author employs "heloma," a pseudo-classic word recently coined by American chiropodists to enhance the dignity of their calling.

LISTER AND HIS ACHIEVEMENT.

By Sir WM. WATSON CHEYNE, Bt., K.C.M.G., C.B., F.R.C.S., F.R.S., &c. London: Longmans, Green and Co. 1925. Pp. 136. 7*s*. 6*d*.

THE first Lister Memorial Lecture, delivered at the Royal College of Surgeons of England on May 14th, 1925, was reported in our issue of May 16th and is here issued in book form. Sir Watson Cheyne tells us in his preface that it was his wish to give a short history of Lister's work, but that he found it impossible to do so within his compass. The lecture illustrates Lister's character and the general plan of his work, while the details of Lister's researches and investigations appear in the form of an appendix to the book. Among the army of those who have tried to minimise human suffering, and have seen success crown their endeavour—an army in whose ranks stand John Howard, Elizabeth Fry, Florence Nightingale, Samuel Romilly, Henri Dunant, and Louis Pasteur—the name of Lister is by no means the least, and it is fitting that one who was one of his earliest pupils and most devoted follower should be the first to proclaim his master's praise in a memorial lecture. The story of Lister's struggles and success is, as Sir Watson Cheyne says, a "most fascinating tale, and its influence on the life and health and usefulness of mankind surpasses all imagination; and it is a true story." There is no reader of our pages but knows what surgery was before Lister's time, and how after his discoveries an operation was in general terms no longer the gate of the grave, but that to life and freedom from pain and suffering. No great discovery has ever been made without much toil, much anxiety, many falls and risings again, and bitter disappointments before success was achieved, and Lister in his work was no exception. The story of his life's work is now old, but it bears re-telling, and no one has told it better than Sir Watson Cheyne. Everyone, whether medical man or layman, should read this lecture, for it is a record of a struggle for the benefit of humanity crowned by success which has rarely been equalled.

PATHOLOGY.

Surgical Pathology. By WILLIAM BOYD, M.D., Professor of Pathology, University of Manitoba; Pathologist to the Winnipeg General Hospital. London and Philadelphia: W. B. Saunders Company. Pp. 837. 45*s.*

THIS book is an attempt to present those aspects of pathology which are of immediate importance to the surgeon. Though much that is necessarily included in works on general and special pathology is omitted, enough remains to make a volume of considerable size. It is difficult to see how it could have been shortened without cramping the author's scheme. The book is divided into two parts dealing respectively with general and special pathology. The chapters on general pathology are short and concise, and we think the author has exercised sound judgment in deciding what to include and what to leave out. Special pathology is treated more fully. The book is copiously illustrated and most of the figures are excellent.

Prof. Boyd is to be congratulated on a work which will assuredly find a place in pathological and surgical libraries. Our only regret is that the price of the volume makes it unlikely that the average student will be able to include it in his personal collection.

A Text-book of Pathology. Third edition. By J. MARTIN BEATTIE, M.A., M.D., Professor of Bacteriology, University of Liverpool; and W. E. CARNEGIE DICKSON, M.D., B.Sc., Director of the Pathological Department, Royal Hospital for Chest Diseases, London. London: William Heinemann. 1925. Pp. 1103. 42*s.*

EXCEPT for a few minor alterations this is a reprint of the second edition of this text-book, reviewed in THE LANCET, 1921, ii., 232 and 904. The only change of any importance is one of format, for the original two volumes are now bound together as one. It is perhaps a convenience to have the whole book in one cover, though it makes a massive volume to hold; the student will probably appreciate a change which reduces the cost of a popular text-book from three to two guineas.

Pathogenic Micro-organisms. Eighth edition. By WILLIAM HALLOCK PARK, M.D., Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical School; ANNA WESSELS WILLIAMS, M.D., Assistant Director of the Bureau of Laboratories, Department of Health; and CHARLES KRUMWIEDE, M.D., Assistant Director of the Bureau of Laboratories. Philadelphia and New York: Lea and Febiger. 1924. Pp. 811. $0.50.

THE eighth edition of this well-known text-book has been thoroughly revised and in part rewritten, and new matter, dealing with immunity, scarlet fever, measles, typhus, and tularæmia, has been added. The classification and nomenclature of the Society of American Bacteriologists have been adopted, so that the book has an authoritative flavour. A large and comprehensive summary table has been added, giving the essential characters of the pathological conditions caused by the commoner organisms. It is a useful table, but the only way to prevent its rapid disintegration by wear and tear would be to mount it as a wall diagram, and it is, unfortunately, printed on both sides of the paper.

ALLEN'S COMMERCIAL ORGANIC ANALYSIS.

Fifth edition. Vol. III. Edited by S. S. SADLER, E. C. LATHROP, and C. A. MITCHELL. London: J. and A. Churchill. 1925. Pp. 782. 30*s.* net.

Volume III. of this well-known work deals more particularly with the analysis of hydrocarbons, bitumen, aromatic acids, and explosives. The section on phenols, contributed by Dr. J. B. Hill, will specially interest medical readers. A considerable amount of new work and modifications in existing analytical methods are described, and the methods for determining the phenol-coefficient of antiseptics are given in full. The cresylic acid group of disinfectants now so widely used, either in the emulsified form or in the soluble state, are dealt with in an adequate manner. The chapter on salicylic acid and the analysis of salicylates and salicylic esters is contributed by Mr. E. Horton, who has written briefly and lucidly. The volume is well and clearly printed, and the illustrations of apparatus form a useful feature of the present edition. No laboratory, whether it be concerned with subjects so wide apart as the analysis of explosives or the examination of food and drugs, can afford to be without the volumes of "Allen" as a work of reference.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 88.)

THE VOLUNTARY HOSPITALS' EVIDENCE.

The British Hospitals Association.

(App. LVII. and Q. 17127–17285.)

EVIDENCE was given on behalf of this Association by Mr. H. Wade Deacon, the Right Hon. Viscount Hambleden, and Mr. J. Courtney Buchanan. They said that the treatment of insured persons by panel practitioners was incomplete because no satisfactory provision for hospital treatment was made in the National Health Insurance Act, 1911. Since the inception of the Act hospitals have always examined and, where necessary, treated, without discrimination between insured and uninsured, cases coming to the hospitals either on reference from their medical attendants or upon their own initiative.

The number of hospitals represented by the Association is 387, of which 117 are in London. The voluntary hospitals have felt very severely the general financial stress since the war, the expenses of most hospitals having increased at least 75 per cent., and many over 100 per cent. The hospitals warmly acknowledge the support that they have received from approved societies, but suggest that much more might be done, in particular with regard to out-patient treatment, for which approved societies make no contributions. The witnesses pointed out that the out-patient special departments of the voluntary hospitals—i.e., the dental, throat, nose and ear, massage, electro-therapy departments, and special clinics—are utilised for special cases, not only in the general diagnosis of the patients' complaints, but also in their subsequent treatment and relief. All of these special departments are extremely expensive to the hospitals.

---

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6); Evidence of the Insurance Committees (May 23rd, pp. 1097–8); Evidence of Various Approved Societies (May 30th, pp. 1135–6); Evidence of the British Medical Association (June 6th, pp. 1184–6; June 13th, pp. 1248–50; June 20th, pp. 1315–6); Evidence of other Medical Bodies (June 20th, p. 1316; June 27th, p. 1348); Individual Evidence (June 27th, p. 1348); Medical Services in the Factory, Ministry of Health Inquiry Room, Evidence of National Sailors' and Firemen's Union and of Loyal Order of Ancient Shepherds (July 4th, p. 36); Evidence of Friendly Societies' Medical Alliance, South Wales and Monmouthshire Alliance of Medical Aid Societies, Friendly Societies' Medical Officers' Union, Association of Approved Societies, Standing Committee of Scottish Insured Women, and Society of Medical Officers of Health (July 11th, pp. 86–8).

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1309.

In suggesting further financial help from insurance funds, the witnesses stressed the point that they did not desire any compulsory levy, nor must there be any contract to treat insured persons as such. It was essential that the voluntary hospitals should preserve their voluntary status.

(Q. 17169.) You do not agree that a statutory requirement that the National Health Insurance funds should be drawn on for the support of the hospitals involves necessarily a certain measure of representation and control?—It is a matter of opinion, I suppose. I think that if there is a compulsory levy then there is reason for some control or some representation and that is rather my objection to anything compulsory in connexion with voluntary hospitals.

Viscount Hambleden thought that it would be dangerous to ask for anything in the nature of a block grant; what was desired was payment for services rendered. It would be objectionable to contract to give preferential treatment to insured persons. The object now is to keep the beds filled with the worst cases. Whether persons are insured or not does not enter into the question from a medical or hospital point of view.

As to financial assistance from insurance funds affecting voluntary contributions, the witnesses pointed out that—

(Q. 17170.) The Government gave a grant of half a million to be distributed by the Voluntary Hospitals Commission to help hospitals. Some people thought that would be the end of voluntary contributions. The contributions are rather bigger than they were before the grant was made.

As to the suggestion that panel practitioners referred to hospital unnecessarily cases which could be equally well dealt with by them in their own surgeries, the witnesses all agreed that no general charge of this sort could be sustained, although there might be individual cases.

The Sheffield Joint Hospitals Council.

(App. LVIII. and Q. 17286–17383.)

This Council represents seven different institutions in Sheffield, each having its own autonomy. It is a consultative and advisory body. Its spokesmen were Sir Henry Hadow and Mr. S. R. Lamb.

They said that a National Health Insurance service is not complete without the coöperation of the voluntary hospitals where the services of specialists and special equipment are available. The Council are encouraging the view that a voluntary hospital should be used largely for consultative and operative work, and a consistent effort is maintained to discourage treatment being given in the out-patient department of our hospitals which could as effectively be given by a panel doctor. In this respect they had no reason to think that there had been any abuse.

(Q. 17206.) The insured people who come to the hospitals in the first place roughly fall into three classes. There are the casualties who come because it is the nearest place; there are the people who want specialist advice, and who are recommended by their panel doctor, and come with his recommendation; and, thirdly, there is a small percentage of people who come because they do not know any better. They live in some poor part of Sheffield; they get ill and frightened, and they say: "I will go to the hospital." In those cases they come to the hospital, but I do not think there is any abuse.

It was probable that the third class were women and children mainly and not insured persons at all.

This Council suggests that the out-of-pocket expenses of maintaining insured in-patients and out-patients in a voluntary hospital should fall on the National Health Insurance funds. In any case, such expenditure by the voluntary hospitals on insured persons should, in future, be the first claim on the quinquennial surplus declared by the Government auditor.

Without wishing to suggest an exact proportion, they hoped that the contributions of societies which at present was about 15 per cent. of the cost of maintenance might go up to, say, 50 per cent.

In connexion with the voluntary character of the hospital administration and the importance that this should not be impaired, it was stated that the moral value of the contributory scheme in Sheffield is very great. It has brought 200,000 workmen into personal touch with the hospital work, and they have formed a Contributors' Council, which is of the greatest value. If grants from insurance or the public funds involved inspection, there could be no objection to this.

(Q. 17316.) On the point of representation, knowing the mind of some of the hospital boards, I think the only thing that would really frighten them would be if there was any chance of having a salaried official put in control of the work. Nothing in the way of supervision or inspection or representation would be anything else but palatable to them.

And, again, the witnesses said that their objection only extended—

(Q. 17370.) As far as having somebody permanently on the spot who was in any way hampering the autonomy of the hospitals. We should not object to anything which corresponds to the Government inspectors who come down to our University.

The Middlesex Hospital.

(App. LIX. and Q. 17384–17482.)

This evidence, given by Mr. A. E. Webb-Johnson and Mr. Walter Kewley, covered to some extent the ground traversed by the previous witnesses in so far as the need for support from insurance funds was in question, and was summarised in the form of a question by Sir John Anderson as follows:—

(Q. 17423.) The voluntary hospitals are meeting a recognised public need; they can only continue to meet that need if they receive financial support on the widest possible basis; they have, therefore, a strong moral claim on any section of the community which is in a position to contribute to their funds: in so far as approved societies have money at their disposal which could be made available for this purpose, the hospitals may properly look to those funds for a measure of support; and, quite apart from that, they are entitled to look to the individual patients, whether insured or no, who benefit by the service that the voluntary hospitals provide, to contribute according to their means.

It was recognised that support to the hospitals from insurance funds, if imposed by statute, must carry with it some inspection to see that an efficient and proper service was being rendered. The strain on the finances of voluntary hospitals did not imply any failure of the voluntary system, but it was due to the fact that the work done is greater in volume than it ever was before.

In regard to insured patients, Mr. Kewley thought there was a tendency on the part of some insurance practitioners to send patients for out-treatment which they could quite well give themselves. The witnesses thought that it was a defect of the Insurance Acts on the one hand, that no satisfactory provision is made for incurable cases which may require treatment over a lengthy period—e.g., cancer; on the other hand, the value of preventive treatment is not sufficiently recognised under the Acts.

Generally, on the need for closer coöperation between the public services and the voluntary hospitals, Mr. Webb-Johnson said—

(Q. 17482.) I would urge that this Commission, in making any recommendation, should not only have in mind the benefit to the insured person. . . . I think in recent years, when the State has been taking a greater part in the treatment of certain diseases, they have not always done it in ways which give promise of the best results. I maintain that for the sake of medical education and research and the advancement of our knowledge, it is to be deplored that when public authorities have assumed responsibility for the treatment of certain classes of disease they have not sought a closer coöperation with our great hospitals and medical schools which are the scientific centres of medical progress. It is to be hoped that these authorities will see the wisdom of establishing some of their treatment centres actually in, or in close association with, our great hospitals rather than in separate institutions.

'BYNIN' AMARA

Trade Mark

A Powerful Tonic and Hæmatinic

'BYNIN' AMARA is of special value in neurasthenia, particularly when associated with low blood pressure, anæmia and atonic dyspepsia; in convalescence it gives that impetus which often enables the system to overcome the aftermath of disease and to recover completely.

'Bynin' Amara has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt in the place of syrup. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

COMPOSITION

Quinine Phosphate	1¼ gr.
Iron Phosphate	2 „
Nux Vomica Alkaloids equal to Strychnine	$\frac{1}{16}$ „
'Bynin' Liquid Malt	1 oz.

DOSE: 2 to 4 fluid drachms in water twice or three daily after meals.

Further particulars and free sample will be sent on request.

THE CANCER VIRUS.

As we indicated last week, the work of Dr. Gye and Mr. Barnard is as significant for its promise as for its performance. "By a theory," said Mendeléeff, "I mean a conclusion drawn from the accumulated facts we now possess which enables us to foresee new facts which we do not yet know." The identification of the virus and the brilliant demonstration of its coöperation with inanimate substances in the production of tumours appears to give us at once a means of testing anything for the presence of either. If a mixture of any substance with a chloroformed extract of the Rous chicken sarcoma gives rise to a tumour when it is inoculated into a fowl, the substance may be presumed to contain the virus. If a chloroformed extract of any tissue inoculated into an animal of the same species along with a fresh extract of a tumour from another species of animal causes a tumour to appear, the tissue may be presumed to contain the accessory substance which Dr. Gye calls the specific factor. At present the experiments throw little direct light on the *de novo* origin of tumours; no tumour appears to have been produced except from a pre-existing tumour. But methods have been found which should quickly illuminate the question of direct causation. When a tar cancer is produced, does the virus come from outside or is it generated in the skin? What are the conditions of time and place under which the specific factor appears? The distribution of the virus can be ascertained and the conditions under which the specific factor arises in the body can be worked out. Especially we shall be most interested to hear what happens when the fundamental experiments are repeated with the substitution for tumours of normal tissues, and tissues in various abnormal states associated with death and regeneration. From the wide distribution of the virus and the absence of specificity, it seems not unlikely that it may be a normal component of the body; it has proved possible in recent years to cultivate whole cells outside the body indefinitely, and Dr. Gye's results may mean that we can now cultivate also some of those components of cells which were dreamed of and dimly seen by Béchamp in his microzymes and Altmann in his bioblasts. If that proved to be the case, the important point in the causation of cancer would be the origin of the specific factor, and the possibilities of successful immunisation would become more remote. Or it may turn out that the virus does not normally exist in the body at all, but is generated within it in something of the same relation to the cells as the bacteriophage has to bacilli. Imagination can run on almost indefinitely, and in this case legitimately, for it is now plainly possible to submit these and many other speculations to experimental test; in this possibility lies the largest importance of the new discoveries.

There are two ways of formulating the problem of the causation of cancer. We may say: "Why do some people have cancer?" or we may say "Why does not everybody have cancer?" It is the same question, but the two ways of setting it out come from different points of view. Most people have started their thinking from the first mode of presentation. There are, however, many reasons for believing that the body does and can resist cancer to some extent, and in all the revision of our present array of facts which the work of Dr. Gye and Mr. Barnard has made so absorbing, it would be well to bear the second point of view in mind as well. A given chain of circumstances is not to be ruled out as a "cause" of cancer if it does not always produce cancer, and like any other mode of growth cancer is a resultant of the reaction between cells and their environment. The whole problem is being steadily cleared up. The demonstration by E. F. Bashford and his colleagues that something may pass out from a carcinoma cell which induces the neighbouring connective tissue to become sarcomatous, is one landmark; the discovery of the Rous chicken tumours was a second; the production of tar cancer by Yamagiwa and Ishikawa was a third. The present discoveries push the experimental study of the cause of cancer a great deal further and reasonably encourage us to hope that the fundamental facts may soon be reflected in human experience.

Throughout the communications published last week in The Lancet both authors regarded their work as requiring in many places confirmatory evidence, and obviously other experiments must be done in certain directions before more than tentative opinions can be formed. We note with pleasure the promptitude with which this situation has been recognised by the trustees of the late Sir William Dunn, who have made a donation to the Medical Research Council of £2000 per annum for a period of five years to be used for the promotion of research work in medicine at the discretion of the Council. The Dunn trustees have already made important benefactions to the advancement of medicine, for they endowed a chair of pathology at Guy's Hospital, and another in biochemistry at Cambridge, erecting a school for the purpose; they have also built and equipped laboratories for the University Medical Clinics at St. Bartholomew's Hospital, St. Thomas's Hospital, and the London Hospital, and have given a new building for the School of Pathology at Oxford. The Medical Research Council, in accepting this generous benefaction, have intimated that for the present they will apply this special Dunn Fund in chief part to the furtherance of the organised studies of filterable viruses which they are supporting, and in particular to the recent developments of work in relation to cancer by Dr. Gye, Mr. Barnard, and their colleagues.

◆

THE BRITISH MEDICAL ASSOCIATION AND INDIVIDUAL DEFENCE.

The Annual Meeting of the British Medical Association had its prelude at Bath on Friday last, July 17th, when Dr. H. B. Brackenbury presided over the Representative Body for the first time; on taking the chair he received an enthusiastic welcome from an assembly which knew how much the activities of the Association of recent years have owed to his enthusiasm and his industry. As will be seen from the report which we are privileged to make of the deliberations of the Representative Body, Dr. Brackenbury had a smooth time, for few of the motions on the agenda put forward by the Council of the Association for ratification provoked dissent, or even led to more than cursory debate. The agenda formed really a record of progress on the administrative side, while the financial statement made with great clearness by the treasurer, Mr. Bishop Harman, was a cheerful one indicating that increased expenditure, even to a record figure, had been accompanied by increased revenue and increased surplus. Two motions of the Council were, however, followed by keen discussion; the first of these was a proposal to establish a bureau for the provision of locum-tenents and assistants, and the second was a request by the Council for an authority from the Representative Body to prepare a draft scheme for a medical defence organisation to be affiliated with the Association. Both these motions had the common origin of a desire to help the recently qualified men and women, as they are recruited by the Association, and when they are faced for the first time with the necessity of finding a sphere in which to exercise their newly acquired rights, and with the accompanying necessity of avoiding professional risks.

With regard to the bureau for locum-tenents, the Council secured endorsement for the policy advocated. The opposition of existing agencies for the provision of locum-tenents and assistants, and for the sale and transfer of practices, was mentioned but discounted as negligible, and the motion for starting the bureau was approved, with the proviso that preferential treatment should be given to members of the British Medical Association. But with regard to the question of the formation of a medical defence association the Representative Body, by a substantial and possibly unexpected majority, declined to permit the Council to prepare a draft scheme along the suggested lines. The question of individual medical defence was threshed out in a debate of a high order. Dr. Morton Mackenzie, chairman of the Organisation Committee, produced strong reasons why the necessary authority should be given to the Council to proceed with the work of medical defence. He urged that they ought to be able to defend their new members from the outset of their professional careers; that the minority in favour of such action had through many years been growing steadily larger; and that in one form of defence—namely, "Optional and Complete"—the officers and organisation of the Association could do all that would be required through the skill and knowledge possessed by the officiate. He stated that less than 7000 members willing to pay an annual fee of £1 would render the undertaking financially secure. These propositions were supported from different points of view by various members of the Representative Body, and it was made clear from the beginning that the position of the Council in again seeking a further decision on a matter which had been settled already on several previous occasions was considered to be justified in view of an apparently growing feeling among the members that they should be offered this form of protection by the Association. But on an amendment being put forward recording the view that individual medical defence was being competently dealt with by various existing bodies, the supporters of that amendment had far the better of the debate. It became clear that the Organisation Committee had been unable to bring forward any arguments which had been calculated to persuade either the Medical Defence Union or the London and Counties Medical Protection Society that their constituencies had anything whatever to gain by coöperation. These bodies were ungracious enough to decline to commit suicide, and seem to have resented the suggestion that members of the British Medical Association should be admitted to the privileges of defence by them at a reduced scale, seeing that they existed for the protection of all qualified practitioners. Various speakers brought up for attention the strong financial position of the existing societies, who are in possession of large memberships and reserve funds, with the implication that a run of bad luck against any new defence organisation established by the British Medical Association would wipe out the young fund or would result in considerable loss to the Association.

But probably the strongest argument of all against the projected departure was that brought forward by Dr. Peter Macdonald and Mr. E. B. Turner, both of whom, though from different angles, pointed out the extremely awkward situation in which the British Medical Association would be placed if a defence body, under the ægis of the Association, should find itself defending a practitioner where the conduct which had to be defended might appear ethically indefensible. This is not a fanciful position; it is one which might well occur. A defence in a court of law might prove successful before a jury which did not consider the ethical side germane to the issues, and yet that very side might later come under the disciplinary notice of the General Medical Council. Such was the line of thought which led to the Representative Body refusing to follow the lead of the Council in the matter of individual defence.

THE EVOLUTION OF HUMAN VISION.

Man's body, like his civilisation, is made up of a vast assortment of parts belonging to varying dates. Some of these parts, such as his heart and lungs, are of ancient lineage; others, such as his facial features and the convolutionary pattern of his brain, represent recent acquisitions. His eye, on which he prides himself and through which he has learned most of what he knows concerning the world in which he lives, must be placed among his older parts. Eyes such as man has, set in sockets so that their axes are parallel, each provided with a specialised area of retina at its distal pole, each furnished with six muscles for external movements and an internal muscle for accommodation, came into existence with the evolution of the Primate stock early in the Eocene period. Binocular vision, or, to be more precise, bimacular or bifoveate vision, is thus much older than the human form; it is an inheritance from a common and distant ancestry which man shares with anthropoid apes and with all forms of monkeys—both those of the Old World and those of the New. The superiority of man's vision lies not in his eyes but in the brain which has grown up behind them. Such we take to be the chief lesson learned by those who were present at the symposium "On the Evolution of Binocular Vision," organised by the Convention of English-Speaking Ophthalmologists, when it met in London last week. The history of man's powers of vision and perception was then opened out in a masterly way by Prof. Elliot Smith, who was followed by Sir Frederick Mott, Prof. Whitnall, of Montreal, and Sir Arthur Keith. A brief report of these speeches is given on another page. In his Bowman Lecture, which we published last week, Sir John Parsons has made clear that the superiority of human vision is psychological, not ophthalmological.

Every infant in the development of its powers of vision bears witness to the truth of Darwinism. At an early stage of fœtal development the eyes swing forwards so that their axes become parallel. Soon after birth the fovea centralis appears. While this minute area of the retina becomes specialised for acute vision, the rest of the retinal cup remains merely a reflex feeder for the central or foveate area. By the sixth week after birth the eyes begin to move together and feed their centres of acute vision. The oculo-motor and cortical centres gradually obtain control of the muscles which move the eyes; by the sixth month a stage has been reached comparable to that possessed by adult monkeys. At the same time the muscles of the neck gain control of the head and can thus keep the eyes directed so that they may follow moving objects. Monkeys alter their field of vision by head movements rather than by eye movements. By the end of its first year a child's vision has reached a stage comparable to that of anthropoid apes—where conjugate movements become more free and temporary accommodation for near objects possible. Stereoscopic vision comes later; it begins to dawn about the third year and goes on improving up to the sixth year. These later improvements in vision depend not on the eye but on the brain. Indeed, ophthalmologists realise that it is hard to tell whether a young child's blindness is due to a defect of the brain or to one of the eyes.

With all these facts constantly before him the physician cannot well doubt the truth of evolution. Man differs from all animals in the perfection of his mental vision; compared to him all other animals are mentally blind. Human vision is Nature's greatest triumph, but it is a triumph reached by the evolution of the brain, not by the attainment of a superiority on the part of the human eye. In the oldest and most primitive of mammals the dominant sense was that of smell; their brains, as Prof. Elliot Smith demonstrated many years ago, were organised on an olfactory basis. In most mammals the nose still remains a master organ. In one fortunate group of arboreal mammals, which made its evolutionary appearance early in the Tertiary part of the earth's history, the eye became the governing sense organ; the axes of their eyes became alined; a spot in the retina, situated at the distal pole of each eye, became specialised for acute sight; bifoveate vision was thus evolved. This new form of vision entailed a reorganisation of all the parts of the brain which had to do with the movements of the eyes, and with the receipt and distribution of visual stimuli. The sight-brain gradually submerged the smell-brain. In the marmoset's brain we can still see an early stage in the evolution of the visual brain; man's brain represents the latest stage of this visual series. Between these two extremes lie intermediate links provided by the brains of various types of monkeys, the cerebral outfit of the gibbon and that of the great anthropoid apes. No one who has swept an eye along this series of brain-forms can doubt the truth of evolution, nor can he fail to convince himself that the superiority of man's vision lies in his brain, for all of these Primate animals are provided with the same kind of eye—all of them are sharers of man's bifoveate vision. As visitors to our Zoological Gardens may observe, the eye movements of the orang are almost human-like in their freedom, yet they are infinitely less effective than those of man. When the orang has swept his foveate centres over an approaching visitor he has learned whether or not there is a prospect of something to eat; with a similar glance a young woman will register the cut and colour of every article on the body of her similar.

While it is manifest that man's vision is a gift of evolutionary processes, the nature of these processes remains obscure. When Darwin's "Origin of Species" was first published, Mr. J. J. Murphy, of Belfast, made the criticism that chance variations could never give rise to an organ such as the eye, which requires exact adjustment in the construction of all its parts. We now realise that the evolution of man's vision involves much more than the eye and its muscles; it involves the nerve centres which control eye movements; it involves the primary optic nerve centres of the mid-brain; it involves areas of the occipital cortex and of the frontal cortex; it involves thousands of adjustments of all parts of the central nervous system. The skull and orbit require readjustment at each stage in the evolution of high vision. How are all of these widely scattered elements concerned in vision moved towards a common functional end during the development of the body? If the eye seems to be the *pons asinorum* of the evolutionists' Euclid, yet it has also proved to be the organ which has yielded the evolutionary key. We know now that the part of the brain which grows out to form the retina can cause any piece of embryonic ectoderm to form a lens; one embryonic element can control the growth of a neighbouring element. We know also, thanks largely to the researches of Dr. Ariens Kappers, that developing nerve cells are brought under influences which cause them to take up new and advantageous positions and arrangements in the nervous system of the embryo. Thanks to the labours of experimental embryologists, we are beginning to know that developing groups of cells of one kind can give out substances—growth hormones—which can and do control the development of other and allied groups of cells. As the new prospect opens out, the evolution of man's vision, if it becomes a still more intricate problem yet becomes one which we may hope to solve. Somehow developmental processes are regulated on a functional basis; there must be a machinery at work in embryo and fœtus for the common control of all parts that are concerned in vision.

PROPOSED UNIT OF CLINICAL PATHOLOGY AT WESTMINSTER HOSPITAL.

The munificence of a private donor, Mr. A. J. H. Carlill, recently placed the sum of £20,000 at the disposal of the board of governors of the Westminster Hospital, and this they have decided to lay out in the establishment of a unit of clinical pathology around which all the work of the hospital shall centre. So to reorganise a teaching hospital as to render it primarily an institution for the study of disease is an important departure, but the difficulties in the organisation of such a scheme are immense. The scheme as now drawn up provides that the unit shall be under the management of a director, assisted by two heads of laboratories. The director will be in supreme command of the work of the unit and upon him will devolve the responsibility of determining in consultation with his colleagues what problems are to be attacked and the manner of the attack. He will have no beds, but will be expected to work in close coöperation with the physicians and surgeons of the hospital. The director will have his own laboratories. Under him will be two assistants, each in charge of their own laboratory. To ensure coöperation between the laboratories and the wards, there will be attached to the director and to both his assistants liaison officers whose duty it will be to see that their respective heads are kept cognisant of the cases in the wards. The arrangements for coöperation between the clinical and the pathological sides would appear to be as complete as they can humanly be made. Ultimately, however, success or failure must depend upon the personality of the staff. The director and to a lesser degree his assistants will necessarily require to be men possessing a thorough mastery of the general principles of pathology in its widest sense, with at the same time a sympathetic and intelligent interest in clinical work. The general trend of medical education in this country has not been such as to produce many men of the type who desire to master the fundamentals of medicine in order that they may the better see their way in treatment.

To many the Westminster scheme will appear to be merely an interesting experiment directed towards the placing of the teaching of pathology upon a new basis. Actually it is far more. This and all other plans of a like nature must stand or fall, not as they affect the teaching and study of pathology, but as they influence the teaching and practice of medicine as a whole.

Annotations.

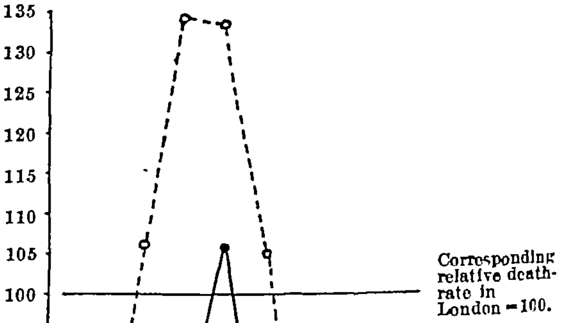
"Ne quid nimis."

INTERNAL MIGRATION AND THE DEATH-RATE.

IN a valuable though admittedly inconclusive inquiry,[1] pursued in a thoroughly scientific way, Mr. A. B. Hill has thrown new light on the problem as to what effect migration of young persons produces on the relative death-rates of urban and rural areas. The general facts obtainable from the Registrar-General's reports and quoted in Mr. Hill's report are fairly well known. Thus, in recent years the total urban death-rate for males is in excess of the rural at all ages under 75, but closely approximates to the rural rate at the age-periods 20–25 and 25–30 years. For females the urban death-rates fall below the rural rates at ages 20–30 years and occasionally also at ages 30–35. Similarly there is a higher death-rate in the rural counties from pulmonary tuberculosis at the ages of adolescence and in early manhood and womanhood, which partially explains the difference between total death-rates in urban and rural areas. The report before us seeks answers to the question why this should be, points out the difficulties inherent in the usual explanations which are offered, and throws light on the contention which has been advanced on good authority that much of the decline in the urban death-rate from phthisis is ascribable to urban migration of the more vigorous units of population and not merely to improved and more abundant food, to better housing, and to diminished dissemination of infection.

Briefly stated, the facts elicited, although not warranting dogmatic statement, appear to show that the high general death-rates from all causes in the rural parts of Essex in adolescence and early adult life are caused by corresponding high death-rates from phthisis, and that this has some relation to the migration into towns of adolescents of both sexes. The report recognises the need for evidence showing, as far as is possible, the life-history of migrants; and by securing the coöperation of clergy and others in Essex, returns have been received from some 55 villages, relating to 402 males and 367 females, of whom about one-half were migrants. It appears likely, in view of the information thus secured, that migrants have found prosperity in the town, and that their return sick to their rural homes is relatively rare. One explanation of the excessive rural death-rates at certain ages can, therefore, probably be ruled out. But it does not follow that the homekeepers —with a high death-rate in early adult life—had intrinsically worse lives. Hence an attempt is made in the report to assess their conditions in rural life as to work, to housing and environment, and to diet. No special evil condition in rural work is revealed; and although rural housing and sanitation are often unsatisfactory, this cannot be held responsible for the high mortality in early adult life, in view of the fact, not mentioned in this report but revealed by the Census figures, that there is terribly greater prevalence of overcrowding in its worst forms in towns than in rural districts.

Much valuable information is given as to rural dietaries, and this part of the report especially deserves study by the social worker. Two-thirds of the income of the Essex families investigated was spent on food, and expenditure on boots must have meant often going short of food. This would appear to have possible direct bearing on the excessive phthisis mortality in early adult life. It is pointed out in the report that the diet would probably be most defective during the first 12 or 14 years of married life, when the father is the only wage-earner, and that this corresponds roughly with the period at which rural death-rates are high; but as against this the curves of growth and weight of Essex children show no signs of malnutrition or lack of growth. If the Essex dietary is, as appears probable, below a desirable level for rural workers, the low phthisis death-rates which are lower than those for London except at ages 20–25 for males and at ages 10–35 for females (see figure below), do not appear to be consistent with the view that malnutrition has borne a large part in the result. It appears highly improbable that the effect of deficient food, even though the deficiency were greatest at these ages, would be limited to adolescence and early adult life. Nor can the "worse housing conditions" in rural districts, to which attention is drawn, be held to explain these differences, for surely their effect would not be shown to such a preponderant extent in early adult life; and as has been pointed out, room-famine is much greater in towns than in rural districts. In towns, furthermore, the opportunities of gross and repeated infection are much more numerous than in rural districts.



Phthisis, 1901–10.
* In ten rural registration areas in Essex.

The report is a careful review of a difficult and intricate problem, presenting many variables, some of them elusive in nature. It should be studied by all social workers as a competent statement of methods of investigation, of ways for overcoming these, and of caution in deducing results.

MONKEYVILLE.

MOST respectably-minded people are deeply shocked at the idea that those who are doubtful about the truth of evolution are numerous enough in Tennessee to pass a law forbidding school teachers to inculcate their pupils with the doctrine that man is in relationship with the apes. It is not a mere question of scientific conformity. Evolution has explained so much to so many of us in the last 60 years that almost everybody finds the world unintelligible without it; linking itself with the idea of progress, it has given all of us a buoyant optimism which is at once a comfort and effective. It seems almost beyond belief that there should be those who would gladly throw overboard such an admirable aid to good living. The prosecution of a young school teacher for breaking a law with which he was presumably well acquainted is, of course, of no great moment. It is the natural consequence of a rash and perhaps defiant act. Nor does it matter very much that such a law should exist. It is generally, if not universally, agreed in the United States that no religious teaching of any kind or description should be given in the public schools, and it is a reasonable corollary that anti-religious teaching should be prohibited too. And if such an understanding exists, it is compatible with common sense and toleration that very wide meanings should be attached to religious and anti-religious. It follows, too, that there are bound to be considerable and sincere differences of opinion as to where exactly the limits of these meanings are to be fixed, and it is possibly the wisest course to determine that in public education they must not even be approached.

Few people now are in the position of the majority 60 years ago in finding serious incompatibilities between science and religion. Difficulties there are and will continue to be, though they are chiefly difficulties of method rather than discrepancies in results. Revelation, for example, is not recognised in scientific circles as an appropriate way of getting information about the material world. But the existence still of a minority who find in the theories of science or, which may be more important, in the way and tone in which they are presented, something seriously discrepant with their particular religious revelation must be recognised, and if in some place they are a majority their will must prevail. Mr. Scopes has been found guilty of violating Tennessee law and (subject to appeal) has been fined one hundred dollars. But very little harm is being done either to the progress of knowledge or to the promotion of sound education. There are other educational agencies for young people besides, and perhaps more potent than, the school teachers, and those of us who do believe in evolution need not be too violent in our natural response to the new shock from America.

EXPERIMENTAL PATHOLOGY OF EPIDEMIC ENCEPHALITIS.

THE literature of the experimental pathology of this condition is a mass of contradictions, the whole dispute turning upon three debated points: The susceptibility or non-susceptibility of the rabbit to the disease, the identity or non-identity of the virus of this disease with that of febrile herpes, and the significance of certain lesions in the brains of experimental animals. On the one hand J. McIntosh, in this country, and a group of workers at the Mount Sinai Hospital in New York, have claimed that the disease is transmissible to rabbits with the greatest ease, whilst, on the other hand, S. Flexner, of the Rockefeller Institute, has stated that in many attempts he has never succeeded in doing this. A middle position has been taken up by C. Levaditi, of the Pasteur Institute, who states that the rabbit is susceptible but is only exceptionally infected successfully, and upholds at the same time the theory that the virus of febrile herpes—which produces indistinguishable lesions—is the same as that of encephalitis. Amongst recent contributors to this vexed study J. R. Perdrau[1] finds that whilst direct transmission of the disease to rabbits by the inoculation of human material is generally ineffective, by certain methods which he has devised the difficulty may be overcome and infection set up. He believes that an "aggressin" is associated with the virus, and that by using an inoculum in which this is artificially increased a "take" may be assured. The substance which he uses for this purpose is the brain of an animal previously inoculated intradermally with herpetic virus and in which organ the virus is presumably present. In addition the number and routes of inoculation of the encephalitic brain are multiplied. By these means two out of three cases of the human disease provided an active virus, and by another manœuvre a third case gave a like result. Perdrau assumes, as is necessary for his explanation of his results, that the herpetic and encephalitic viruses are identical. This is not in the least certain, and is ill-supported by clinical evidence; it is, moreover, difficult to be certain that the alleged aggressin does not contain a certain amount of active herpetic virus, or that the very intensive inoculation employed may not have been a determining factor. Flexner,[2] who, together with H. L. Amoss, has extensively studied the two conditions, definitely takes the view that the herpetic virus is a ubiquitous material and a very likely contaminator in such experiments. He does not, moreover, consider it merely a special variety of the encephalitic virus, and shows that whilst the serum of animals inoculated with the former exerts a neutralising action upon this virus, the serum of human cases which have recovered from encephalitis has no such effect. It cannot, therefore, be said that this crucial point has yet been cleared up.

HYGIENE IN FACTORIES.

ANYONE who compares the spirit pervading the latest annual report[3] on factory inspection with one of its forerunners of 25 years ago cannot fail to note how the work of the inspectorial staff has become less that of enforcement of statutory requirements by penal prosecutions, and more that of advice and help to employers who are coming to regard the inspectors as friendly experts rather than inquisitorial detectives. Although during the period under review trade was depressed, bright spots are reported: electrical developments, motor transport, and railway plants were busy; the output of carpets, linoleum, and furniture was brisk; fish-curing was prosperous; while new industries started, such as the Schmiedal process of making sulphuric acid and refining crude petroleum from Persia. Labour-saving devices continue more and more to improve working conditions, quicken production, and minimise occupational risks. Factories again increased in number and workshops declined, and for the first time on record the former with 142,494 outnumbered the latter with 133,729; the figures portray the tendency for small places to be absorbed by the big and for power to be used to replace human effort. The section dealing with safety tells how accident prevention is being scientifically approached through attention directed to different types and causes of mishaps. Owing to an alteration in the legal definition of an accident the records are not comparable with those of previous years; but we regret to find no effort made to express accident occurrence as a rate either of those employed in different industries or of man-shifts worked—what is possible for the mining industries ought at least be attempted for factory employment. Again, attention is directed to the vast number of accidents which are unpreventable by any known protection, and can only be guarded against by safe working methods adopted by the workers themselves and also by foremen and managers. Instances are quoted of the beneficial results of "safety-first" work; both frequency rates and severity rates always fall. The outstanding wonder is that a policy which gives such great financial returns is being adopted with comparative slowness. One movement worthy of note as combining safety and health is the substitution of abrasive wheels for natural grindstones. The abrasive wheel is safer as regards accidents due to bursting, and does not, during grinding, generate fine silica dust; fortunately operations are performed better and more quickly on abrasive wheels. The abolition of the old-time grindstone and with it of "grinders' rot"—i.e., tuberculous silicosis—cannot now be far distant. The increased demand for electric accumulators for wireless sets has led to adoption of new regulations to protect workers from lead poisoning. Dust in cotton cardrooms has again called for investigation, as appliances, introduced 10 to 15 years ago for removing it, and with it "strippers' asthma," have been losing their efficiency; progress, in the light of experience gained, seems certain. More and more interest is reported to be taken in standards of illumination, and the department is lending scientific aid to employers to demonstrate how improvements may be effected; already the minimum standards recommended by the Departmental Committee on lighting are receding into the background as economically insufficient.

THE ENGLISHMAN'S HEIGHT.

WHAT is the height of the average Englishman? Is it changing gradually? Is evolution, as tested by this and other measurements of the human body, proceeding in England to-day? These are some of the questions which were discussed by Sir Arthur Keith in a recent paper before the Royal Institution of Great Britain, entitled Concerning the Rate of Man's Evolution. The difficulties attendant on a biometric survey of any nation or group of nations are notorious. Before the war it was commonly supposed that the average Englishman stood 5 ft. 8 in. in height, but figures gathered since have shown that is too high by at least 2 in. A popular pocket cyclopædia gives the average height of a man as 5 ft. 7 in., and if the heights of children are considered, with which Sir Arthur Keith was not, incidentally, concerned, the discrepancies between various authorities are even more marked, for striking differences have been shown to exist for country and town children, rich and poor children, in the same country.[1] If the different European nations are considered, figures from trustworthy sources go to show that the Belgian school-boy of 7, for example, is on the average 2 in. shorter than an English boy of the same age. These examples have been quoted to show how difficult it is to carry out satisfactory biometric investigations, even among living subjects, and when it comes to the measurement of fossilised remains, such difficulties are obviously accentuated. Putting aside these difficulties, however, Sir Arthur Keith was concerned with the broad question of whether evolution is proceeding at an appreciable rate at the present day in this country. Here geological and anthropological evidence appears to be at variance. On the one hand, the minute comparison of 50 skulls taken from English graves known to be at least 1000 years old with skulls of a corresponding number of men and women who had lived in England during the eighteenth and nineteenth centuries seemed to show that evolution is now at work in our midst. The palate presents the chief changes, and other modifications are seen in the configuration of the bones of the nose and jaws. The cause for this appears to lie deeper than a mere disuse of the jaws, for the changes described appear to affect about only 30 per cent. of the modern population, although all live on approximately the same dietary. Such biometric evidence, however, is distinctly opposed by certain geological discoveries, and particularly that at Galley Hill in 1888. "The Galley Hill man," says Sir Arthur Keith, "was of the modern European type," and yet on geological evidence the stratum in which this skeleton was found fixes its age at hundreds of thousands of years, and even the more modern "cultural" investigations, based upon the workmanship of the implements found in the same strata, would assign to the Galley Hill man an antiquity of 100,000 years. If the primitive human types discovered at Piltdown, Heidelberg, Java, and Rhodesia are considered in view of the fact that there is broad agreement as to the early dates at which these types lived, then evolution must have been comparatively rapid to produce modern man. As such anthropological evidence accumulates it forces the conclusion that the geological arguments connected with the Galley Hill man must be rejected. It is obvious, however, that much confusion still remains to be cleared up, and perhaps present-day anthropologists will consider their successors of many generations hence and bury an account of the measurements of an average Englishman of the twentieth century in the foundations of, say, a new Waterloo Bridge.

HOSPITAL COOKS AND COOKERY.

THAT hospital food is always monotonous and often badly cooked is a venerable complaint, sometimes true and sometimes less true. Of late, however, the difficulty of getting food for hundreds of people well cooked has been conspicuously less than that of getting it cooked at all. Most hospitals are finding that cooks, male or female, are exceedingly shy and elusive creatures, not easily tempted even by what would once have seemed a wickedly lavish display of Treasury notes. The Metropolitan Asylums Board, which has 19 large hospitals in its charge, has suffered sore things in its kitchens. In 14 of them there were 57 vacancies in six months; at one hospital the kitchen staff has been incomplete for nearly two years; in another, over a period of 11 months no assistant cook could be induced to stay for more than a month. In some of these cases there may have been exceptional local drawbacks, but this unhappy experience suggests either that there is something wrong with the pay or the conditions of service or that the expectations and outlook of the kitchen staff are unreasonable. However this may be, the Board have determined upon heroic measures. Cooking is to become (as it ought to be) a dignified service, almost, in fact, a learned profession. The invidious word "cook" is to be discarded; the artists who have hitherto suffered under that designation will henceforth be "kitchen-superintendents," and will have at their disposition aspirants for the *cordon bleu* with the title of "assistant-superintendents." These presiding officers of the kitchen (they are to be "qualified women") will be paid £200 a year, rising to £220, they will have a month's holiday in the year (about double the allowance of the doctor in the wards upstairs), and will be arrayed in a uniform the style and cut of which will probably require consideration as grave as that recently given to the outdoor costume of the registered nurse. "Kitchenmaid" has never had a very gracious sound—it conjures up too graphically visions of Shakespeare's "greasy Jane that keels the pot," and it is now to be replaced by the more euphonious title of "kitchen-assistant," with £55 a year "and all found" attached to it. If by the establishment of a culinary hierarchy, in which "kitchen assistants" may become "assistant-superintendents" and eventually "superintendents," the Asylums Board can solve its difficulties, it will have deserved well of all forms of "institution." Great numbers of clever and competent women, even when [illegible] hold a cookery certificate, find it impossible to earn £200 a year, plus board and lodging, and such terms ought to attract a class which, in addition to being reasonable and contented, can cook a potato, and actually knows when a rice pudding is "done." We understand that in some general hospitals an expert "food adviser" has been appointed, whose duties comprise the choice of an adequate variation of the diets, the collection of the food at the best markets, and supervision of the kitchen staff, with the responsibility for seeing that the food is efficiently cooked, and that it is served to the wards hot and convenient for distribution to the patients.

POOR-LAW HOSPITALS AND TUBERCULOSIS.

REFORM of the Poor-law, although placed in the forefront of the political programme, has not yet taken very definite shape. The Minister of Health announced in Parliament on May 27th that he proposed to begin by transferring administrative functions without altering the present law. Two circulars (607 and 607A), dated July 21st, issued to boards of guardians and municipal councils respectively, indicate one direction in which the Ministry of Health is proposing to secure effective coöperation within the limits of the existing law. There are at present in Poor-law institutions a number of cases of pulmonary tuberculosis at a stage which affords reasonable prospect of arrest of the disease. Such cases would be better in a residential institution run by a local authority under a tuberculosis scheme. To attain this measure of coöperation the Ministry makes the reasonable suggestion to boards of guardians that they should appoint the local tuberculosis officer as consultant at the Poor-law institutions. The guardians would then have the benefit of the clinical services of an officer with personal knowledge of the medical history of the patient. The tuberculosis officer would be requested to examine the patient either before admission or as soon as possible after admission to the Poor-law hospital, with a view to consider whether the case is one for sanatorium treatment. The Ministry goes on to advise boards of guardians, contemplating additional accommodation for tuberculous patients, to consider whether this provision should not be ordinarily undertaken by county and borough councils. Further accommodation for the treatment of non-pulmonary tuberculosis is earnestly commended to the attention of these councils, as well as a proper orthopædic scheme for dealing with the crippling deformities of children. The recommendations of the Ministry, if carried out, will anticipate in one direction the need for Poor-law reform.

THE sudden death occurred last week at the age of 67 of Mr. F. E. Beddard, D.Sc., for many years prosector to the Zoological Society of London. Frank Evers Beddard, who was educated at Harrow and New College, Oxford, made his first mark in science as one of the naturalists who worked out the material collected by the *Challenger* expedition. Many of his contributions to mammalian anatomy were thoroughly original, and he was elected to the Royal Society while quite a young man. He wrote the volume on mammals in the Cambridge Natural History, and several interesting monographs on such subjects as the classification of birds, the geographical distribution of animals, and the natural history of whales. To THE LANCET he sent frequent and illuminating notes on zoology, in which his use of simple language for the description of technical matter was remarkable.

INDEX TO "THE LANCET," VOL. I., 1925.

THE Index and Title-page to Vol. I., 1925, which was completed with the issue of June 27th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXII.

THE TREATMENT OF EPIDEMIC DIARRHŒA.

ALTHOUGH the prevalence of infantile diarrhœa in the hot months has been noted for centuries, there is still no common agreement as to its cause. While it is generally accepted that bottle-feeding, heat, and infection all play a part, it is still a matter of dispute whether it is purely a zymotic disease or whether the remaining factors are primary. Probably the majority of cases are due to an extended form of the diarrhœa (usually fermentative) which occurs in infantile dyspepsia and are, therefore, more in the nature of a chemical disturbance of digestion, the rôle of bacteria being only secondary. With the facts so uncertain, it is better, from the practical viewpoint, while taking every precaution to exclude extraneous infection (by milk, dirty utensils, and so forth) to pay equal attention to the composition of the food and, in particular, to the avoidance of mixtures too rich in sugar, especially when combined with much fat. Lately, suspicion has been cast on the whey.

The fact that epidemic diarrhœa is limited to hot weather makes it evident that the effects of a high temperature must be accounted the most important of exciting causes. It is probable that heat not only influences unfavourably the digestion and absorption of food, but also by depressing vitality helps to lower the power of resistance.

The Clinical Picture.

The clinical picture varies according to the severity of the condition. In the milder cases the diarrhœa is accompanied by slight fever without much general disturbance. In the more severe types, of which the "choleraic" represent the extreme, the symptoms lose their purely alimentary character and become widespread. This change is dependent mainly upon loss of fluid and upon toxic absorption. Evidences of this are found in the rapid loss of weight, inelastic skin, pinched features, sunken eyes and depressed fontanelle, rapid feeble pulse, and anuria. Toxic symptoms are chiefly conspicuous in the nervous system in the form of restlessness, drowsiness, and finally coma. Another leading symptom of this class may be "air hunger," evidenced by rapid, deep, and often irregular breathing. In detailing therapeutic measures one would first urge the necessity both of studying the clinical picture as a guide to treatment and of watching these patients from hour to hour, in view of the rapid advance.

There are two distinct phases—the acute one, where the main indication is elimination by stopping all food and evacuating the bowel; and the later one, which the main problem is to find a suitable diet.

The Management of a Case.

1. *General Measures.*—If there is much collapse a mustard bath (at 100° to 105° F.) should be given. After this the child should be put to bed and kept warm in a well-ventilated room or even in the fresh air. The clothing should be light, and scrupulous cleanliness in the child's person should be secured. Napkins must be changed frequently and removed from the room. Excoriation of the buttocks can be prevented by cleanliness and the use of starch and boric powder; in the event of the buttocks becoming sore an efficacious application is lime-water and olive oil in equal parts. The baby should be bathed twice daily with tepid water and the mouth carefully swabbed with cold water.

2. *Elimination.*—If there is abdominal distension with fever and offensive stools, castor oil should be given, or, if this is vomited, calomel gr. ¼ may be

protection, and can only be guarded against by safe working methods adopted by the workers themselves and also by foremen and managers. Instances are quoted of the beneficial results of "safety-first" work; both frequency rates and severity rates always fall. The outstanding wonder is that a policy which gives such great financial returns is being adopted with comparative slowness. One movement worthy of note as combining safety and health is the substitution of abrasive wheels for natural grindstones. The abrasive wheel is safer as regards accidents due to bursting, and does not, during grinding, generate fine silica dust; fortunately operations are performed better and more quickly on abrasive wheels. The abolition of the old-time grindstone and with it of "grinders' rot"—i.e., tuberculous silicosis—cannot now be far distant. The increased demand for electric accumulators for wireless sets has led to adoption of new regulations to protect workers from lead poisoning. Dust in cotton cardrooms has again called for investigation, as appliances, introduced 10 to 15 years ago for removing it, and with it "strippers' asthma," have been losing their efficiency; progress, in the light of experience gained, seems certain. More and more interest is reported to be taken in standards of illumination, and the department is lending scientific aid to employers to demonstrate how improvements may be effected; already the minimum standards recommended by the Departmental Committee on lighting are receding into the background as economically insufficient.

THE ENGLISHMAN'S HEIGHT.

WHAT is the height of the average Englishman? Is it changing gradually? Is evolution, as tested by this and other measurements of the human body, proceeding in England to-day? These are some of the questions which were discussed by Sir Arthur Keith in a recent paper before the Royal Institution of Great Britain, entitled Concerning the Rate of Man's Evolution. The difficulties attendant on a biometric survey of any nation or group of nations are notorious. Before the war it was commonly supposed that the average Englishman stood 5 ft. 8 in. in height, but figures gathered since have shown that is too high by at least 2 in. A popular pocket cyclopædia gives the average height of a man as 5 ft. 7 in., and if the heights of children are considered, with which Sir Arthur Keith was not, incidentally, concerned, the discrepancies between various authorities are even more marked, for striking differences have been shown to exist for country and town children, rich and poor children, in the same country.[1] If the different European nations are considered, figures from trustworthy sources go to show that the Belgian school-boy of 7, for example, is on the average 2 in. shorter than an English boy of the same age. These examples have been quoted to show how difficult it is to carry out satisfactory biometric investigations, even among living subjects, and when it comes to the measurement of fossilised remains, such difficulties are obviously accentuated. Putting aside these difficulties, however, Sir Arthur Keith was concerned with the broad question of whether evolution is proceeding at an appreciable rate at the present day in this country. Here geological and anthropological evidence appears to be at variance. On the one hand, the minute comparison of 50 skulls taken from English graves known to be at least 1000 years old with skulls of a corresponding number of men and women who had lived in England during the eighteenth and nineteenth centuries seemed to show that evolution is now at work in our midst. The palate presents the chief changes, and other modifications are seen in the configuration of the bones of the nose and jaws. The cause for this appears to lie deeper than a mere disuse of the jaws, for the changes described appear to affect about only 30 per cent. of the modern population, although all live on approximately the same dietary. Such biometric evidence, however, is distinctly opposed by certain geological discoveries, and particularly that at Galley Hill in 1888. "The Galley Hill man," says Sir Arthur Keith, "was of the modern European type," and yet on geological evidence the stratum in which this skeleton was found fixes its age at hundreds of thousands of years, and even the more modern "cultural" investigations, based upon the workmanship of the implements found in the same strata, would assign to the Galley Hill man an antiquity of 100,000 years. If the primitive human types discovered at Piltdown, Heidelberg, Java, and Rhodesia are considered in view of the fact that there is broad agreement as to the early dates at which these types lived, then evolution must have been comparatively rapid to produce modern man. As such anthropological evidence accumulates it forces the conclusion that the geological arguments connected with the Galley Hill man must be rejected. It is obvious, however, that much confusion still remains to be cleared up, and perhaps present-day anthropologists will consider their successors of many generations hence and bury an account of the measurements of an average Englishman of the twentieth century in the foundations of, say, a new Waterloo Bridge.

HOSPITAL COOKS AND COOKERY.

THAT hospital food is always monotonous and often badly cooked is a venerable complaint, sometimes true and sometimes less true. Of late, however, the difficulty of getting food for hundreds of people well cooked has been conspicuously less than that of getting it cooked at all. Most hospitals are finding that cooks, male or female, are exceedingly shy and elusive creatures, not easily tempted even by what would once have seemed a wickedly lavish display of Treasury notes. The Metropolitan Asylums Board, which has 19 large hospitals in its charge, has suffered sore things in its kitchens. In 14 of them there were 57 vacancies in six months; at one hospital the kitchen staff has been incomplete for nearly two years; in another, over a period of 11 months no assistant cook could be induced to stay for more than a month. In some of these cases there may have been exceptional local drawbacks, but this unhappy experience suggests either that there is something wrong with the pay or the conditions of service or that the expectations and outlook of the kitchen staff are unreasonable. However this may be, the Board have determined upon heroic measures. Cooking is to become (as it ought to be) a dignified service, almost, in fact, a learned profession. The invidious word "cook" is to be discarded; the artists who have hitherto suffered under that designation will henceforth be "kitchen-superintendents," and will have at their disposition aspirants for the *cordon bleu* with the title of "assistant-superintendents." These presiding officers of the kitchen (they are to be "qualified women") will be paid £200 a year, rising to £220, they will have a month's holiday in the year (about double the allowance of the doctor in the wards upstairs), and will be arrayed in a uniform the style and cut of which will probably require consideration as grave as that recently given to the outdoor costume of the registered nurse. "Kitchenmaid" has never had a very gracious sound—it conjures up too graphically visions of Shakespeare's "greasy Jane that keels the pot," and it is now to be replaced by the more euphonious title of "kitchen-assistant," with £55 a year "and all found" attached to it. If by the establishment of a culinary hierarchy, in which "kitchen assistants" may become "assistant-superintendents" and eventually "superintendents," the Asylums Board can solve its difficulties, it will have deserved well of all forms of "institution." Great numbers of clever and competent women, even when they hold a cookery certificate, find it impossible to earn £200 a year, plus board and lodging, and such terms ought to attract a class which, in addition to being reasonable and contented, can cook a potato, and actually knows when a rice pudding is "done." We understand that in some general hospitals an expert "food adviser" has been appointed, whose duties comprise the choice of an adequate variation of the diets, the collection of the food at the best markets, and supervision of the kitchen staff, with the responsibility for seeing that the food is efficiently cooked, and that it is served to the wards hot and convenient for distribution to the patients.

POOR-LAW HOSPITALS AND TUBERCULOSIS.

REFORM of the Poor-law, although placed in the forefront of the political programme, has not yet taken very definite shape. The Minister of Health announced in Parliament on May 27th that he proposed to begin by transferring administrative functions without altering the present law. Two circulars (607 and 607A), dated July 21st, issued to boards of guardians and municipal councils respectively, indicate one direction in which the Ministry of Health is proposing to secure effective coöperation within the limits of the existing law. There are at present in Poor-law institutions a number of cases of pulmonary tuberculosis at a stage which affords reasonable prospect of arrest of the disease. Such cases would be better in a residential institution run by a local authority under a tuberculosis scheme. To attain this measure of coöperation the Ministry makes the reasonable suggestion to boards of guardians that they should appoint the local tuberculosis officer as consultant at the Poor-law institutions. The guardians would then have the benefit of the clinical services of an officer with personal knowledge of the medical history of the patient. The tuberculosis officer would be requested to examine the patient either before admission or as soon as possible after admission to the Poor-law hospital, with a view to consider whether the case is one for sanatorium treatment. The Ministry goes on to advise boards of guardians, contemplating additional accommodation for tuberculous patients, to consider whether this provision should not be ordinarily undertaken by county and borough councils. Further accommodation for the treatment of non-pulmonary tuberculosis is earnestly commended to the attention of these councils, as well as a proper orthopædic scheme for dealing with the crippling deformities of children. The recommendations of the Ministry, if carried out, will anticipate in one direction the need for Poor-law reform.

THE sudden death occurred last week at the age of 67 of Mr. F. E. Beddard, D.Sc., for many years prosector to the Zoological Society of London. Frank Evers Beddard, who was educated at Harrow and New College, Oxford, made his first mark in science as one of the naturalists who worked out the material collected by the *Challenger* expedition. Many of his contributions to mammalian anatomy were thoroughly original, and he was elected to the Royal Society while quite a young man. He wrote the volume on mammals in the Cambridge Natural History, and several interesting monographs on such subjects as the classification of birds, the geographical distribution of animals, and the natural history of whales. To THE LANCET he sent frequent and illuminating notes on zoology, in which his use of simple language for the description of technical matter was remarkable.

INDEX TO "THE LANCET," VOL. I., 1925.

THE Index and Title-page to Vol. I., 1925, which was completed with the issue of June 27th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXXII.

THE TREATMENT OF EPIDEMIC DIARRHŒA.

ALTHOUGH the prevalence of infantile diarrhœa in the hot months has been noted for centuries, there is still no common agreement as to its cause. While it is generally accepted that bottle-feeding, heat, and infection all play a part, it is still a matter of dispute whether it is purely a zymotic disease or whether the remaining factors are primary. Probably the majority of cases are due to an extended form of the diarrhœa (usually fermentative) which occurs in infantile dyspepsia and are, therefore, more in the nature of a chemical disturbance of digestion, the rôle of bacteria being only secondary. With the facts so uncertain, it is better, from the practical viewpoint, while taking every precaution to exclude extraneous infection (by milk, dirty utensils, and so forth) to pay equal attention to the composition of the food and, in particular, to the avoidance of mixtures too rich in sugar, especially when combined with much fat. Lately, suspicion has been cast on the whey.

The fact that epidemic diarrhœa is limited to hot weather makes it evident that the effects of a high temperature must be accounted the most important of exciting causes. It is probable that heat not only influences unfavourably the digestion and absorption of food, but also by depressing vitality helps to lower the power of resistance.

The Clinical Picture.

The clinical picture varies according to the severity of the condition. In the milder cases the diarrhœa is accompanied by slight fever without much general disturbance. In the more severe types, of which the "choleraic" represent the extreme, the symptoms lose their purely alimentary character and become widespread. This change is dependent mainly upon loss of fluid and upon toxic absorption. Evidences of this are found in the rapid loss of weight, inelastic skin, pinched features, sunken eyes and depressed fontanelle, rapid feeble pulse, and anuria. Toxic symptoms are chiefly conspicuous in the nervous system in the form of restlessness, drowsiness, and finally coma. Another leading symptom of this class may be "air hunger," evidenced by rapid, deep, and often irregular breathing. In detailing therapeutic measures one would first urge the necessity both of studying the clinical picture as a guide to treatment and of watching these patients from hour to hour, in view of the rapid advance.

There are two distinct phases—the acute one, where the main indication is elimination by stopping all food and evacuating the bowel; and the later one, which the main problem is to find a suitable diet.

The Management of a Case.

1. *General Measures.*—If there is much collapse a mustard bath (at 100° to 105° F.) should be given. After this the child should be put to bed and kept warm in a well-ventilated room or even in the fresh air. The clothing should be light, and scrupulous cleanliness in the child's person should be secured. Napkins must be changed frequently and removed from the room. Excoriation of the buttocks can be prevented by cleanliness and the use of starch and boric powder; in the event of the buttocks becoming sore an efficacious application is lime-water and olive oil in equal parts. The baby should be bathed twice daily with tepid water and the mouth carefully swabbed with cold water.

2. *Elimination.*—If there is abdominal distension with fever and offensive stools, castor oil should be given, or, if this is vomited, calomel gr. ¼ may be

tried; but in cases in which the diarrhœa is already profuse further purgation will only do harm. Early irrigation of the colon with normal saline is advisable in all cases as it hastens the effect of the cathartic and removes offensive material. This should be done two to three times a day on the first day and only once a day afterwards, for prolonged treatment of this kind will merely exhaust the child.

3. *Restorative Measures.*—Thorough evacuation, no food, and plenty of water form the essentials of treatment in the first 24 hours. A bottle should be kept filled with half strength normal saline and offered to the baby when awake. Though the degree of recovery by this method alone is often surprising, in most cases further measures are necessary to make good the dehydration. The simplest is the subcutaneous injection of 2 to 3 oz. of normal saline (at temp. 105°) into each side of the abdominal wall, though the amounts should be regulated by the rate of absorption. 5 per cent. glucose is an alternative for infusion.

In urgent cases saline may be injected into the peritoneal cavity, a method which allows of large amounts being given quickly, and of more complete absorption. This is a safe procedure, under aseptic precautions, if care is taken to relieve abdominal distension and to empty the bladder; 6 to 12 oz. at a temperature of 100° may be given in this way, slowly, by the gravity method.

Of stimulants, brandy (♏ 5–10) well diluted, given every one to two hours, is the best. The value of many of the stimulants often advocated is debatable: but if there is acute circulatory collapse with rapid pulse, ♏ 1–2 of 1/1000 adrenalin chloride hypodermically is certainly effective. Camphor in olive oil (gr. ¼ to ♏ 5) may be tried in desperate cases.

The injection of 10 to 15 c.cm. of human blood, with the idea of increasing immunity, has seemed beneficial in some cases, but further evidence is required.

4. *Diet.*—All food must be withheld for 12 to 36 hours until the acute symptoms subside, boiled water, weak tea, or weak barley-water being allowed. Starvation at this stage is essential

The next stage, the return to food, presents difficulties. What may suit one case may not suit another, because, as already stated, the causal agents are not always the same. While ideally, perhaps, the mode of treatment should be suggested by the predominant type of organism (proteolytic, fermentative, &c.), this is not a practical proposition. Though no definite rules can be laid down, certain general lines may be indicated. Whatever kind of food is chosen it is important (*a*) to give small feeds at first, (*b*) to make additions slowly, (*c*) to note the effect of increases of food on the temperature, the general condition, and the stools, though it is not always wise to wait for too great an improvement in the latter. Milk is best avoided until the temperature is nearly normal, and, in all cases, when feeding is recommenced, fat is best omitted entirely at first unless albumin milk is used. Some help may be gained from the child's reaction to starvation. If there has been a decided improvement and a fall in temperature, success is often attained on a mainly protein diet, especially in those cases where the stools have been strongly acid. This may be given in the form of skimmed milk, fresh, or perhaps better, dried (such as Cow and Gate or Trufood), added cautiously to the water, giving at first ¼ to ½ oz. every second feed and gradually increasing if improvement is maintained. The next step, the stools now being formed, is to add sugar in small amounts. The safest variety of sugar is undoubtedly dextri-maltose, as it tends to ferment less easily than lactose. Finally, a half-cream dried milk or ordinary milk and water mixtures may be embarked upon.

As an alternative albumin milk may be prescribed; in dried form this has proved useful in my hands. Its value lies in the fact that while containing little sugar and whey the protein content is high and lactic acid is added. Whey may be well tolerated after the starvation period, but while satisfactory in milder types, it does not always prove so in the severest ones and is hardly to be recommended as a routine. To cases developing an infective colitis, recognised by the persistence of the temperature and by the continued frequency of the stools which become mucoid and contain blood, it is better to give foods containing little residue, and if skimmed milk does not agree, better results may be obtained by a malted milk or whey with added Benger's food. Fat is badly tolerated and should be ordered with care. Finally, if breast milk is available it may be given on the second or third day, and is superior to any other form of feeding.

5. *Drugs.*—Though they have their use, too much reliance must not be placed on medicines to the exclusion of the more important general measures. Opium is the most valuable, and is specially indicated when the stools are very frequent and there is much pain; it is perhaps of the greatest service in the choleraic cases. It must, however, be used with discrimination, and as a rule should not be prescribed in the early stages before the bowel has been emptied, if there is collapse, or if the motions are small and offensive while the tongue is furred. It may be exhibited as tinct. opii (♏ ⅙ at six months, ♏ ⅓ at one year) four-hourly, or as pulv. ipecac. co. (gr. ⅙ at three months. gr. ¼ at six months) six-hourly.

After the initial stages when the diarrhœa is less but still persistent, small six-hourly doses of castor oil are valuable (ol. ric. ♏i. with mucilage). Another plan is to alternate this mixture with a combination of hyd. c. cret. and pulv. ipecac. co., a dose of each being given three times a day. Bismuth, if ordered in large doses (gr. 5 to 20 from a few weeks to a year old), may be effective, especially when the large bowel is affected.

Special Symptoms.

Persistent Vomiting.—After a preliminary wash-out of the stomach with a weak sod. bicarbonate solution vomiting is, in many cases, controlled merely by reducing the feeds in size. If even small sips of water are rejected, feeding by mouth must be stopped and recourse had to saline injections to supply the necessary fluid. Drugs are of little value with the exception of morphia, which may be given hypodermically (gr. 1/100 at three months) in urgent cases when other methods have failed.

Hyperpyrexia.—A persistently high temperature (105° F.) should be relieved either by tepid sponging or by the application of a cool pack. This latter method helps to control not only the high temperature but also the nervous symptoms which accompany it. If restlessness is extreme sedatives may be given.

Ketosis.—Where there is clinical evidence of this state (stupor, air-hunger, acetonuria) it is best treated by giving plenty of fluid and, specifically, 5 per cent. dextrose solution (intravenously), which provides a more rational and safer treatment than alkalies.

Tenesmus.—This is best relieved by rectal irrigation with warm saline, combined, if need be, with doses of silver nitrate (gr. 1/12 to 1/6) or opium by mouth.

Prophylaxis.

The comparative immunity of the breast-fed is a testimony to the importance of breast-feeding, and if a child is on the breast it is unwise to wean during hot weather. Babies who have had previous dyspeptic disorder so readily fall victims to the disease that great care should be taken to see that prescribed mixtures are rational ones, and that upon the slightest sign of indigestion immediate steps are taken to correct this and to modify the feeds to suit hot-weather needs. Over-feeding by giving excess of milk, instead of added water, to satisfy thirst must be guarded against. The food should be prepared with care, fresh milk should be boiled, and if not beyond suspicion should be replaced by a dried milk. Attention to the details of the nursing care and hygiene of the child and his protection against the excessive heat by light clothing and adequate ventilation of the rooms contribute not only to his comfort, but also to the prevention of what may prove a serious disease.

Charing Cross Hospital.

Special Articles.

SOME GENERAL REFLECTIONS ON PUBLIC HEALTH ADMINISTRATION.

BY J. H. L. CUMPSTON, M.D. MELB., D.P.H. LOND.,
DIRECTOR-GENERAL OF HEALTH, COMMONWEALTH OF AUSTRALIA.

II.—THE MEDICAL PRACTITIONER AND PUBLIC HEALTH.*

IN that magnificent statement—"An Outline of the Practice of Preventive Medicine" (1919)—Sir George Newman embodies "the law and the prophets" of preventive medicine. In his summary of the present status and future prospects of preventive medicine he says:—

> "It is clear that such a policy as that which is here outlined calls for an adequate medical service and the appropriate administrative machinery. The foundation of a medical service is the medical practitioner. He is its pivot, its anchor, its instrument. If he is competent it has the first surety of success; if he is ineffective or ill-equipped it must fail" (*pp.* 100–101),

and he also quotes the Editor of THE LANCET as saying:—

> "The prevention of disease is as much the rôle of the practitioner as is the cure and care of patients."

About the same period the present writer, addressing the Australasian Medical Congress said:—

> "The medical practitioner cannot escape his responsibility to the nation. He has the knowledge, or is, at least, in the best position to acquire the knowledge; he has the patient under his hand from first to last; he has the confidence of the patient and his friends; and, of all conceivable agents, he is in the best position to apply effective measures of preventive medicine. He must accept his responsibility and must accustom himself to a state of mind in which he would feel the same shame at a secondary case of infectious disease in a family amongst his patients as he would at sepsis after an operation. The aseptic conscience must be sensitive to all forms of preventable disease, not merely those due to errors in surgical technique."

The General Medical Council of Great Britain has recently revised the medical curriculum in the interests of the

> "ever-widening subject of preventive medicine. The Council recommends that the subject should be a pervading influence all through the curriculum, affecting every subject in it, so that the student naturally and almost unconsciously adopts in his daily practice of medicine the attitude and spirit of prevention."

If the importance of the general practitioner is so great that "if he is ineffective public health must fail," the first inquiry that must be made is what actual steps have been taken by either the national governmental authorities or the elected governing directorate of the medical profession to ensure that the general practitioner is worthy of his high calling and that he is sufficiently well-trained, well-organised, and well-supported to be effective. It can be said at once that in neither the United Kingdom, the United States, nor Australasia has a complete organisation been developed which makes full use of the general body of the profession or gives in any way a *satisfactory* plan *for* the transferring of the edifice of public health to its proper "foundation"—the medical practitioner. There is no doubt as to the necessity for devising such a plan, and it is interesting to review certain attempts which have been or are being made towards this end.

The State of Alabama, U.S.A.

Perhaps the most striking, certainly the most interesting, although not the most valuable, attempt to attain this end is found in the legal code of statutes of the State of Alabama. The basic organisation of the State public health system is found in the following extracts from the Health Laws:—

> "The Medical Association of the State of Alabama is the State Board of Health. The State Board of Censors of said Association shall be known as the State Committee of Public Health. The boards of censors of county medical societies in affiliation with the Medical Association of the State of Alabama shall be known as county boards of health of their respective counties, including all incorporated municipalities therein, and shall be under the general supervision and control of the State Board of Health."

The actual status in practice of this arrangement is best indicated by the preface to the "Public Health and Medical Laws of Alabama" (1920 edition), written by Dr. S. W. Welch, State health officer.

> "The State of Alabama has been magnanimous in a legislative way to her medical profession. Perhaps in no other Government of the world has a like spirit of confidence in, and generosity to, her medical men been crystallised into law."

In support of this declaration the following examples are given:—

> 1. The State has wholly and entirely entrusted to her organised medical men the right of deciding who shall be admitted to their ranks, thus enabling them to elevate the standard of qualification of the practitioners of medicine in the State to such plane as they may desire, thereby protecting the people against the evils of ignorance, quackery, and dishonesty.
> 2. She has provided that her health boards—State and county—shall consist of medical men exclusively, and endowed these boards with the important legal function of administering the health laws and regulations of the State, the counties, and the incorporated cities and towns.
> 3. She has confided to the organised profession the right of naming all medical health officials—State, county, and city—and by doing so has not only placed the selection of these officials in the hands of those most competent to judge as to their fitness, but has thereby widely divorced her public health system from politics and from commercial influence.
> 4. She has provided her medical men, not only with the privilege, but with the right of practically applying through their organised bodies, State and county, whatever sanitary knowledge they may acquire to the prevention of disease and to the protection of the health and lives of the people.
>
> "It is hoped that every member of the profession in the State will avail himself of the opportunity which this pamphlet affords of getting full information as to the medical laws of the State. When that has been done, *the close coördination between the scheme of organisation* of the profession and the public health system and laws of the State will be obvious. Then every member of the profession in the State will know his duty, and knowing, should stand ready to discharge it faithfully and conscientiously."

That the control of the Medical Association over the administration is complete is illustrated in the case of county medical officers of health:—

> "No county health officer-elect shall assume office until his election shall have been approved by the State Committee of Public Health."

The Medical Association, as is indicated in the quotation above, has power of issue of certificates to practise medicine—i.e., it is not only a registration body but an examining and qualifying body.

> "The Board of Censors of the Medical Association of the State of Alabama is constituted a State Board of Medical Examiners."

One passage in the "Law Regulating the Practice of Medicine" reads as follows:—

> "The State Board of Medical Examiners may revoke a physician's certificate of qualification to practise medicine for any of the following: . . . (3) Being guilty of unprofessional conduct of a character likely to deceive, defraud or injure the public in matters pertaining to health."

As might be expected under the circumstances the law preventing the treatment of diseases of human beings by any system of treatment whatsoever by any person who has not obtained a certificate of qualification from the State Board of Medical Examiners is very precise and very rigid. On the other hand, it has been thought wise by the legislature to create special administrative bodies—e.g., the Alabama Tuberculosis Commission, the Child Welfare Department, independent of the State Board of Health and with separate statutory powers, while the regulation of the employment of minors in industry is confided to the State prison inspector.

---

* Part I. appeared in THE LANCET of July 11th, and Parts III. and IV. will be given in subsequent issues.

While the purpose and the intention of this legislation appear to have arisen from an early realisation of the proper place of the medical practitioner in the public health machine, yet, in my opinion, the results obtained by this procedure have not been such as to justify the substitution for the recognised democratic manner of Government control of a system in which Government delegates its functions and its authority to a private organisation. Moreover, in practical working, many minor departures from the original idea have been introduced, until now the system actually in operation does not in practical detail differ much from the ordinary working of a Government department.

Dr. Ghapin, the veteran Health Commissioner of Providence, comments thus on this method :—

> "One plan to avoid political entanglements, which has been tried in several States, is to give the medical societies a share in the management of the health department. It is dangerous and unwise to give to non-representative bodies a share in the Government. Moreover, medical men as a body are not skilled in preventive medicine. Only great benefits, not to be otherwise secured, would warrant such a delegation of authority. It must be remembered that medical politics and medical log-rolling are at times as pernicious as any other form of partisanship."

The American Medical Association has fully acknowledged as its duty the encouragement of public health ideals amongst its members, and the dissemination of important information not only to its members but to the general public. Dr. Frederick Green, the secretary of the Council on Health and Public Instruction of the American Medical Association, laid down the position in 1914 as follows :—

> "There is to-day serious need of an increased appreciation of the social responsibilities of the medical profession. As these are largely responsibilities of physicians in the aggregate rather than as individuals, it is important that they should be discussed in medical organisations and should become the basis of intelligent action. . . . Since the relation of physicians to the public cannot be that of dictators or rulers, and since the power for restriction and regulation must always lie in the will of the majority, there remains only a single relation which physicians as a class can maintain towards the general public—namely, that of teachers."

These are extracts only from an informative article, but they serve to indicate the basis of the present policy of the American Medical Association—viz., a collective rather than an individual responsibility, and an educational rather than a political policy. In the interpretation of these ideas the American Medical Association has rendered most important service—e.g., in the exposure of pseudo-therapeutic frauds, of quasi-medical impostures, the publication of much public health literature in the form of reprints and pamphlets, and most recently the publication of a popular journal, *Hygeia*, of a high order of excellence.

Australia.

In Australia there has been an interesting series of steps towards the realisation of the ideal inclusion of the general practitioner as a working organic element in the public health system. At the time of the influenza pandemic the Commonwealth Health Department summoned a conference of representatives of the State Departments of Health and representatives of the State branches of the British Medical Association. This was a new departure from established practice, as these conferences had previously consisted of officials only. In 1921, when plague appeared in Brisbane, this precedent was followed and a similar conference summoned. In 1922, at a conference on venereal disease control, the same constitution was adopted. In this way the importance of the practising profession in all public health matters was acknowledged and has been definitely established.

When, in 1921, the Commonwealth Department of Health was created, it was considered important to maintain regular contact with the organised profession, and the suggestion was made that the Commonwealth Director-General of Health might attend and an unofficial talk might be held with the Federal Committee of the branches of the British Medical Association in Australia on the occasion of each of its meetings, held every six months. These talks, informal and perhaps inconclusive, have continued until now; and, while there is little to show of a tangible kind, there is much to cause satisfaction in two directions. The much closer association developing between the official departments and the controlling body of the medical profession offers promise of a practical expression to the acknowledged community of interest. In addition, there has been close consideration by the profession of the individual responsibility and opportunity of training physicians in matters of public health administration and possible reform; as a result the following has been adopted by the Federal Committee of the British Medical Association in Australia for the consideration of the whole profession :—

> "In no State is the service of the practising practitioner officially utilised for the prevention of diseases to any degree consistent with his knowledge and opportunity. Any scheme to rectify existing conditions (in respect of public health generally) must have as its immediate ideal . . . the linking up of the general practitioner into active participation in the administrative scheme and the steady inculcation of the ideal of prevention rather than of carrying out regulations, into both the actively administrative and actively practising members of the profession. On the medical side the unit is the medical practitioner, whether in general or special practice or acting as medical officer to industrial or school organisations or to institutions. In addition to the treatment of his patients he should—
>
> "(i) Notify to his district health officer on prescribed forms: (*a*) All birth, stillbirths, and miscarriages. Objection has been taken to this suggestion on the grounds that it would be impossible to secure notification of miscarriages in single women. The force of this objection is recognised. If it is so strong that notification of miscarriages would be a dead letter, it had better be dropped. On the other hand, it must be recognised that the notification proposed is to a medical not lay authority and that if the medical profession is to take its share in the lessening of criminal abortion, some such step will ultimately be necessary. Confidential notification of miscarriages by married women would frequently lead to the institution of treatment for otherwise overlooked maternal syphilis. Notification of stillbirths to the district medical officer would have the same effect. Notification of births to such authority would be of great value statistically and would assist in infant welfare objects. (*b*) All deaths. At present the death certificate is given to the relatives or undertaker and is largely formal. This practice would continue for burial purposes, but in addition a confidential notification to be made to the medical officer, as is at present done in Switzerland, could often show the relation of the cause of death to a previous infection in a way that is impossible now. This would afford more accurate statistical information and would make available a mass of information that is at present unutilised for public health purposes. The need is so greatly felt that some States already have a private arrangement between the principal medical officer of the State and the registrar of deaths, by which the latter forwards to the former copies of certificates relating to deaths from infectious causes. The present suggestion would gain the same object in a much more direct and far-reaching way. (*c*) All cases of communicable disease prescribed by the regulations. (*d*) All cases of mineral (lead, &c.) or organic (alcohol, &c.) poisoning.
>
> "(ii) Order in writing prescribed methods of concurrent and terminal disinfection in infectious cases. The methods would be prescribed by the State health authorities (with the conference of State health authorities suggested later in the scheme these would soon become uniform in different States). The prescribed methods would be printed on different forms for different diseases. The practitioner would only need to sign one of these and hand to householder just as quarantine officers in different ports now hand fumigation orders to captains of vessels which require fumigation.
>
> "(iii) Carry out the prescribed methods for the prevention of the spread of infection by contacts or carriers—i.e., throat swabs, collection of urinary and fæcal specimens, &c. At present some of these are done by nursing or sanitary inspectors. It would be far quicker and more efficient for them to be done by the practitioner seeing and treating the case.

"(iv) Examine school-children in particular districts by arrangement with the district health officer and education authorities. Such a provision would chiefly apply to country schools and might occur with regard to a particular threatened epidemic or with regard to physical examination of school. It would afford opportunity of coöperation of educational and health authorities in special cases.

"(v) Carry out other health duties as prescribed from time to time by regulations or as requested by district health officer. The objection has been raised that such a proposal puts the practitioner too much under the control of the district health officer. It must be remembered that in the discussion of a general scheme, some such clause must be inserted, to leave room for possible developments beyond the instances above cited. The term 'requested' as opposed to 'prescribed' is used to emphasise the fact that mutual coöperation between district health officer and practitioner is requisite to the scheme, rather than the purely formal carrying out of legal enactments.

"*Note.*—For all such services rendered the practitioner will receive fees prescribed by regulation. There would thus be an incentive to him to increase his activities; the more interest he showed in preventive measures, the more his remuneration; part-time medical officers would be abolished; all men in practice would be on the same level in relation to departmental administration."

If this proposal be adopted it will be a new move in public health progress. The enrolment of the private practitioner in the public health army is by no means a new idea, but the idea of making him the medical officer of health to his own patients will be a new move even if it is not a new idea.

Qualifications to these Proposals.

The present writer, giving evidence before the Royal Commission on National Health Insurance, after dealing with the above proposals, made the following qualifications:—

"All experience shows that modern preventive medicine is ignoring the general medical practitioner to its own disadvantage, and that it is now essential for the success of preventive medicine that all practising physicians should become actively engaged in the official campaign against the occurrence of disease and death. It is, however, necessary that: (1) The practitioner shall not be expected to undertake any duties which are not on the lines of his daily medical work; (2) the practitioner shall be adequately paid for all work done; (3) the practitioner shall be prepared to accept freely both advice and direction from trained public health officials on matters outside the range of his own experience or within the range of official necessities; (4) the practitioner should be prepared to accept discipline in professional matters relating to public health from an official body of his professional colleagues in place of the police court discipline now provided by various statutes.

"There is one phase of the relationship between the medical practitioner and any administrative organisation which requires consideration. It is an important item in the unwritten code of medical etiquette that a diagnosis declared to a patient by the doctor shall not be questioned in the presence of the patient and shall not be lightly altered even by a senior consultant. While the presumption of infallibility may in the past have been an important adjunct to the doctor's treatment, the general state of public enlightenment renders this now unnecessary and the attitude of the profession in relation to the sanctity of the original diagnosis as a matter of ethics might well be revised. Another related matter is the practice of some doctors of giving the patient a wide margin of benefit in the issuing of medical certificates for official purposes. It is very desirable that medical certificates of sickness or disability should be more reliable than they now are in many cases."

Here, then, on the one hand, is the idea, already widely accepted and frequently reiterated—the correlation of the medical practitioner with public health administration. On the other hand are three different types of practical expression of this idea. In Alabama the whole responsibility for public health administration was originally entrusted to the organised profession. The American Medical Association is doing much in developing a policy of intelligent collective action in public health work, but has not taken, as an association, any defined place in the public health scheme. The Federal Committee of the British Medical Association in Australia is working towards the objective of making the whole army of medical men in the country the fighting force in the public health campaign. This will have—if successful—several good results. It will increase the interest of every medical practitioner in the prevention of disease; it will compel the public health specialist to supply reliable information which means that he must know his subject thoroughly; it will give to the departmental authorities a solid backing of support which will enable them in their turn to compel attention, respect and, most important, funds, from Parliament and Government.

The administrative interpretation of the principles of public health in practical form as one of the functions of Government can hardly be considered a legitimate field for the organised association of the practising profession or even for its members individually. The devotion of part of the resources of the collective profession to the education of doctors and public in the principles and technique of public health is a legitimate and most valuable form of auxiliary enterprise, but it does not utilise to the full the great potential striking value of the medical army. This can only be achieved by enlisting that army as voluntary members and training them to coherent action with uniform and intelligent inspiration—the training, inspiration, and direction being supplied by a headquarters staff of trained specialists in which the whole army has full confidence.

Whether any one of these modes, or something quite different, is ultimately found to be the best, all are agreed with Sir George Newman that "an adequate medical service must seek to fulfil and conjoin all the varied elements of a national health policy, environmental and personal. There must be no divorce between the epidemiologist and the practitioner."

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for 1921 of a group, including four metropolitan boroughs and the county borough of West Ham:—

Name of borough.	Mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. (from childbirth.
Kensington ..	178,700	16·2	13·0	0·83	1·6	3·2	25	75	1·7
Poplar	167,300	22·9	12·1	1·20	1·3	3·5	37	72	1·3
Westminster ..	130,000	11·6	11·8	0·99	1·5	3·0	27	59	3·1
Stoke Newington	52,020	10·6	11·2	0·85	1·4	2·2	27	68	2·3
West Ham ..	317,400	22 7	11·5	1·19	1·3	3·2	—	78	1·7

Kensington.

Dr. James Fenton reports several "bests on record" for 1921. These include the death-rate from tuberculosis, the infant death-rate from enteritis, the maternal mortality-rate, and the death-rate among illegitimate infants. The majority of the inhabitants of North Kensington are poor people, whilst in South Kensington such persons constitute only a small portion of the population. This fact is reflected in the birth-rate of 21·7 for North Kensington and 9 2 for South Kensington. During the year the council took successful proceedings against a medical practitioner for failing to notify a birth.

One of the most difficult of the housing problems in Kensington is the sanitary control of houses let in lodgings. There are 5000 tenement houses—i.e., houses let to more than one family without being specially adapted for the purpose. Of these 2904 are on the register of houses let in lodgings. About 55,000 persons occupy these houses. Worse than these are the houses let in so-called furnished rooms, and Dr. Fenton records with satisfaction the gradual diminution of these latter. Thus, in 1912, there were 187, and at the end of 1924 there were 83. A table is given in which the infant mortality-rates in the tenement houses and mews dwellings are compared. There are 2091 mews dwellings in the borough. The annual figures are small and have to be used with caution. The infant mortality in private houses was 43 in North Kensington, 61 in South Kensington. The infant mortality in tenement houses was 90 in North Kensington, 47 in South Kensington. The infant mortality in mews dwellings was 72 in North Kensington, 41 in South Kensington. During the last three years there has not been a single death from enteritis in the South Kensington mews dwellings, the majority of which are over garages instead of stables. During 1924 there were also no infant deaths from enteritis in North Kensington mews dwellings, in the case of which only a few of the stables have been converted into garages. The good results as regards enteritis in 1924 are attributed by Dr. Fenton mainly to the cold and rainy summer. Before any conclusions are arrived at as to the effect of housing conditions upon infant mortality, "consideration," says Dr. Fenton, "must be given to the fact that negligent, careless, ignorant, and poverty-stricken parents generally drift into the worst type of tenement house and mews dwelling." Infants in the better-class homes are not visited by the health visitors. During 1924 these "above-standard" births number 768, with 19 deaths, giving an infant mortality of 24. This is to be compared with an infant mortality of 93 for the remaining infants.

A table shows that the decline in the mortality of illegitimate infants has been very marked in recent years. Thus, during the period 1911 to 1921, the infant mortality of illegitimate children was much more than double that of the legitimate, while in 1922, 1923, and 1924 the rate for illegitimate children was 135, 127, and 97 respectively, as compared with 82, 70, and 75 for all infants. Antenatal work continues to make progress. Thus, for 2140 births coming within the scope of the council's scheme, there were 1199 expectant mothers who attended the antenatal clinics of the Queen Charlotte's Nurses' Home and the infant welfare centres.

Poplar.

Dr. F. W. Alexander's thirty-second annual report includes those of the chief health visitor, the senior medical officer of the Royal College of St. Catherine (Dr. H. K. Waller), and the council's dental surgeon. Artificial sunlight has been administered to a number of children and the results are so encouraging that permanent accommodation is being obtained for its much more extensive use. A permanent building is also to be erected for the installation of extended plant for the manufacture of electrolytic disinfectant fluid. There is an increasing demand for this disinfectant, and it is in regular use for the three swimming-baths. The arrangements with the Seamen's Hospital, Greenwich, for carrying out bacteriological examinations (other than tubercle) continues to be satisfactory. Plans are being prepared for an up-to-date maternity and child welfare clinic in High-street, Poplar, and also for the erection of observation wards. Provision will be made for a dental clinic and for artificial light treatment.

Dr. W. C. P. Smith, the tuberculosis officer, reports that the new premises for the dispensary, Wellington-road, Bow, have now been in use for a full year and that they have given every satisfaction. The comparatively quiet surroundings are much appreciated after the turmoil of the main road. The question of a branch dispensary in High-street, Poplar, is still under consideration. Cases of lupus are given Finsen light treatment at the London Hospital. The council pays a charge of 5s. per application. Seventeen cases received 440 applications during the year.

Dr. Waller, in his report, gives an account of a case which illustrates some of the disadvantages of institutional treatment of an infant suffering from malnutrition. The history of the baby was something as follows. It was born in a lying-in hospital and its weight was inaccurately registered at 9 lb. As it only weighed 7 lb. 10 oz. on the seventh day it was taken to the out-patient department of a children's hospital at a distance and breast-feeding was replaced by artificial feeding. It did not thrive, however, and was admitted into a Poor-law hospital on the fifteenth week where it improved rapidly up to the twenty-second week. For the next seven weeks it lost weight as an in-patient of a convalescent home. For the next five weeks its weight remained stationary at a resident childrens' nursery. At 35 weeks it was brought to the centre and weighed 11 lb. Its dieting and management with the help of the health visitor was found to be a simple matter. The visitor encouraged the distracted mother. The improvement was uninterrupted, and at 52 weeks the baby's weight was 20 lb. Dr. Waller emphasises the need for accurate weighing at birth and the importance of the health visitor's work in the home.

Westminster.

Dr. Francis J. Allan, in his farewell report, gives an interesting contrast of conditions and death-rates in the city of Westminster when it was re-incorporated 25 years ago and at the present time. At the former period the large slum areas north of the Strand with a density in parts of 900 to 1200 persons per acre was being dealt with. Underground habitations were common. The law is now more stringent and in 1924 only seven instances of infringement were discovered. In the earlier period the water-supply of houses was restricted and seldom carried above the ground floor. The abolition of the system of an extra charge for water laid on to upper floors helped matters. Now every tenement house has water on each floor. Refuse was only collected weekly or fortnightly, and this with the restricted water-supply inevitably led to a high infant mortality from diarrhœa. In 1903 the Westminster Health Society was inaugurated and has been active ever since. Needless to say, there have been great improvements in the death-rates. The male death-rate from all causes has declined from 16·5 in the first quinquennium of the century to 14·4 in 1921–24; the female from 12·5 to 9·6; and the infant mortality from the neighbourhood of 120 to an average of slightly over 50 for the last three years. The death-rate among children between the ages of 1 and 5 has been halved, while the death-rate among children from 5 to 15, always low, has remained practically constant throughout the whole period. There is little change in the death-rate of infants in the first week of life, but a marked improvement in the neonatal mortality. Amongst other matters mentioned by Dr. Allan is the improvement in the tailoring and dressmaking workshops in the northern areas. Better ventilation has been secured and the Gas Light and Coke Company have coöperated in providing proper methods for carrying off fumes.

Stoke Newington.

Dr. Henry Kenwood would like to see provision made for dental treatment in connexion with the maternity and child welfare scheme. Owing to the risk from small-pox two small shelter flats have been provided for the temporary accommodation of families during the disinfection of their houses. There appears to be a prejudice on the part of the public against occupying these shelters unless the circumstances indicate grave danger. Dr. Kenwood evidently thinks they might be used with advantage in cases other than small-pox. The tuberculosis officer (Dr. L. U. Young) says there is no apparent improvement in the housing conditions of the area served by the dispensary. General practitioners are sending up new cases to the dispensary in increasing numbers.

The children attending Stormont House School have responded well to open-air treatment. The Invalid Children's Aid Association have been instrumental in obtaining accommodation at convalescent homes for delicate and tuberculous children, but the need for a local home for advanced and urgent cases of tuberculosis still exists. Dr. Sophia Jackson-Smith (maternity and child welfare officer) says very few babies suffer from malnutrition but a large number from overfeeding and too frequent feeding. Education in food values is needed, she says, and the older girls should be taught cookery in a practical manner. Very few parents are unable to provide suitable clothing, but nevertheless many children suffer from unsuitable clothes. The toddlers do not get enough sleep. Antenatal work makes progress. Two women gave birth for the first time to living babies, one after three and the other after four stillbirths. More houses are needed, not on account of the industrial development of Stoke Newington, but to cope with overcrowding. Dr. Kenwood complains of the failure of the scavengers to keep the refuse carts covered with the tarpaulins provided for the purpose.

West Ham.

Dr. F. G. Collins only took up his duties last September. Thirty-one cases of encephalitis lethargica were notified, in three of which the diagnosis was not confirmed. One death of an infant girl occurred; eight of the 28 cases appear to have made a complete recovery. The remainder are under treatment suffering from various nervous symptoms and debility. As the introduction to a propaganda campaign, a Christmas card from the West Ham Council was distributed to each of the scholars in the elementary schools with the headline "Health is better than Wealth," and nine health maxims inside.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 11TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 88; scarlet fever, 1635; diphtheria 806; enteric fever, 49; pneumonia, 775; puerperal fever, 61; cerebro-spinal fever, 11; acute poliomyelitis, 8; encephalitis lethargica, 52; dysentery, 4; ophthalmia neonatorum, 183. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from enteric fever, 35 from measles, 63 from whooping-cough, 9 from scarlet fever, 95 from diphtheria, and 18 from influenza. In London itself there were no deaths from influenza; deaths from diphtheria numbered 7, from whooping-cough 16.

NO TAX ON TOURISTS IN FRANCE.—The French Parliament has fixed at 68 francs (10 francs for students and workers) the cost of the identity card which must be obtained by foreigners staying in France for a period exceeding two months. The card once obtained will be valid for two years. The Office National du Tourisme may take some credit for the preferential treatment thus accorded to bona-fide tourists.

ASSOCIATION STOMATOLOGIQUE INTERNATIONALE.—At a meeting to be held at 11, Chandos-street, *London*, W., on Monday, July 27th, at 8.30 P.M., the following societies will be represented: Royal Society of Medicine, Section of Odontology; British Dental Association; Public Dental Service Association; and the Incorporated Dental Society. The chair will be taken by Mr. A. Templar Barritt, L.D.S., dental surgeon to the French Hospital. After an address of welcome by Sir W. Arbuthnot Lane, papers will be read on the following subjects: Public Dental Service in England, by Mr. J. Clifford Wing, L.D.S. Professional Education of Medical Specialists in the British Isles (Stomatologists and Dentists), by Mr. J. Lewin Payne, M.R.C.S., L.D.S. Stomatology, Public Health, and the Qualifications for Specialists in Medicine in 1925 in Relation to International Social Problems, by Mr. Alfred J. Asgis, D.D.S., clinical professor of stomatology, New York Polyclinic Medical School. National Health Insurance (Dental Phase), by Mr. Fred. Butterfield, secretary of the Incorporated Dental Society and member of the Dental Board of the United Kingdom. The President of this Association is Dr. Chompret at 182 rue de Rivoli, Paris.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BATH.

THE ninety-third annual meeting of the British Medical Association opened at Bath on July 17th, when the Representative Body met at 10 A.M. in the Grand Concert Hall of the Pump Room. Dr. H. B. Brackenbury occupied the chair.

Municipal Welcome.

During the course of the morning the Mayor of Bath, Alderman Cedric Chivers, J.P., visited the meeting to convey a welcome to the Association. He said that this gathering was, perhaps, the most important and certainly the largest company that had ever honoured the city with its presence; the bells of the Abbey had been rung in welcome, and he was glad to have an opportunity to recognise publicly the great service and vital value of the medical profession to civilisation. There was no need to extol the beauties of the city and locality; his task was to offer the fullest hospitality to the meeting, an offer bounded only by the space and material at the disposal of the municipal authorities. Dr. Brackenbury, in reply, said that the Association had looked forward for years with peculiar pleasure to this visit to a historic and beautiful city renowned for those principles of health and education for which the medical profession stood.

REPRESENTATIVE MEETING.

FRIDAY, JULY 17TH.

After the usual formal business the meeting passed a vote of deep regret and condolence with the President, Dr. F. G. Thomson, who was prevented by illness from taking his place at the gatherings. Mr. C. P. Childe was elected a vice-president of the Association, in recognition of his services as President 1923–24, and Mr. R. G. Hogarth of Nottingham was elected President for 1926–27. In 1927, the year of the Lister Centenary, the Association will meet in Edinburgh. Mr. F. G. Hallett was elected an honorary member in gratitude for his valuable services, particularly in connexion with the preparation of the Roll of Honour. The affiliation with the Canadian Medical Association was celebrated by the election of two of the Canadian delegates as Vice-Presidents: Dr. A. Primrose, Dean of the Medical Faculty in Toronto and chairman of Council, C.M.A., and Dr. F. N. G. Starr, honorary secretary of the Annual Meeting, 1906. At an extraordinary general meeting held in the afternoon the articles of the Association were duly amended to allow of the affiliation.

In moving the adoption of the annual report of Council, Dr. R. A. Bolam referred to the serious losses in personnel suffered by the Association during the year, particularly that of Dr. Haslip, the ex-treasurer, the fruit of whose wise judgment they continued to reap. He referred to the new "Sir Charles Hastings Fund," established through the generosity of a member of Council to form a reservoir from which urgent needs experienced by members of the Association might be relieved without undue formality.

The New House.

In approving the report of Council under the heading "New House of the Association," the Chairman referred to the award of the gold medal of the Association to Dr. Bolam, who responded to prolonged applause by expressing his deep appreciation of the honour done to him and his vision of the new house as rallying point for members in the Kingdom and the Empire, and a focus of activity which should be of the greatest value to the profession and the State. He urged those to come not to be afraid of undertaking heavy responsibilities and carrying out the larger plans for the headquarters, but to look with a generous eye to the future.

The Representative Body then placed on record its deep appreciation of the services rendered in connexion with the selection, preparation, and opening of the new house in Tavistock-square. The resolution is to be framed and hung in a suitable place within the house.

Dr. Bolam, in acknowledging these motions and the congratulatory speeches of Sir Jenner Verrall and Dr. J. A. Macdonald, said that it was largely a question of time and place and circumstance that any one man should be on the spot and be able to do the service necessary. He paid a tribute to the special and well-nigh indispensable qualities and knowledge of the financial secretary, Mr. L. Ferris Scott. It had been astounding and most gratifying to see the devotion of all officials, senior and junior, to the work of the Association during the trying period of stress, and the Association might well feel proud of the spirit animating all its workers.

Financial Position.

Mr. N. Bishop Harman, the treasurer, in moving the adoption of the financial report, pointed out that there was a surplus of over £8000 obtained on a record expenditure of £113,917. The forecast for the year 1924, published in the annual report of Council for 1923–24, showed an estimated surplus for the year of £5500; the actual surplus realised as shown by the books was £8923, a result accounted for almost equally by increases over the estimates in the revenues from subscriptions and advertisements.

A New Journal of Pædiatrics.

Dr. J. A. Macdonald, chairman of the Journal Committee, reported a very successful year, and announced that the Committee proposed to found a subsidiary journal of children's diseases to publish certain articles on this subject that were not suitable for the general paper, but could find no adequate place in any existing journal. It was hoped that the publication, a monthly one, would be self-supporting, and the principle might subsequently be extended.

Research Scholars.

Dr. C. O. Hawthorne, in submitting the report of the Science Committee, said that the Association might well congratulate itself on the work accomplished by its scholars. In particular the holder of the Ernest Hart Memorial Scholarship, Dr. A. J. Copeland, had succeeded in finding a new local anæsthetic with all the virtues and none of the perils of cocaine. The Committee was much indebted to the specialists who inspected the work of these scholars, and reported on them, and also to those who acted as judges in the award of prizes. The library was being increasingly used by members.

Mr. H. S. Souttar added his congratulations on the work of the research scholars, and pointed out that one of them, Dr. H. W. Cairns, had obtained a Hunterian professorship at the Royal College of Surgeons of England as a result of his work whilst holding a B.M.A. grant.

Mr. E. B. Turner said that the grant allowed for scientific work was much too small.

Standards of Remuneration for Teachers and Research Workers.

Dr. Hawthorne mentioned two projects not yet ready for discussion by the Representative Body, viz.:—

1. The establishment of a standard of remuneration for laboratory and research workers to the effect: Proposed that whole-time (*a*) non-professorial medical teachers, and (*b*) medically qualified laboratory or research workers, should be grouped into three grades as defined below, and with the salaries as stated:—

Grade III.—Comprising those who are junior workers temporarily employed on probation: no person shall remain in Grade III. for more than three years. That the minimum salaries for Grade III. shall be as follows: First year, £300; second year, £350; third year, £500.

Grade II.—Comprising laboratory or research workers or teachers who have had experience in Grade III. or in work of a similar character, and who are permanently and exclusively employed as such.

Grade I.—Comprising those of Grade II. whose qualifications or duties justify a position of seniority in status and a higher remuneration. That the minimum salary for Grade I. shall be £750 per annum; that after the probationary period (i.e., Grade III.) has been completed, dismissal should be possible only on grounds of neglect of duty, improper conduct, or incapacity.

Proposed that non-professorial medical teachers and medically qualified laboratory or research workers holding part-time appointments should receive remuneration, for the time engaged, at the rate of not less than £000 per annum.

A Book of Remedies.

2. The publication of a book describing the nature and quality of new and non-official medicines, similar to that published by the American Medical Association. The object which the A.M.A. has in view in publishing its book is to disseminate information among members of the profession in the United States relative to new and non-official medicines and medicinal preparations. For admission to the book any one of these must comply with the rules of the A.M.A. which prescribe, inter alia (i.) that the composition of all articles must be declared; (ii.) that generally speaking articles advertised to the public will not be accepted; and (iii.) that an article will not be accepted concerning which the manufacturer makes unwarranted, exaggerated, or misleading statements. The Council understands that the activities of the A.M.A. in this direction meet a real need on the part of the profession in the United States.

These proposals will come before the Representative Body next year. Dr. Hawthorne urged members to consider whether such a publication were necessary or advisable, if so, whether it were a suitable activity for the Association and whether it were a justifiable expenditure.

Oblique Advertising.

The chairman of the Ethical Committee, Dr. R. Langdon Down, presented the reconsidered recommendations as to oblique advertising which the Committee hoped would provide a compromise satisfactory to the press and the profession. The report recommends that practitioners who desire to discuss in the lay papers matters relating both to medical science and policy and to the health and welfare of the public should make it a condition of publication that laudatory editorial comments or headlines relating either to the contributor's professional status or experience shall not be permitted; that his address or photograph shall not be published; and that there shall be no unnecessary display of his medical qualifications and appointments. There is a special claim that practitioners of established position and authority shall observe these conditions, for their example must necessarily influence the action of their less recognised colleagues. Discussions in the lay press on disputed points of pathology or treatment should be avoided by practitioners; such issues find their appropriate opportunity in the professional societies and the medical journals. The report goes on to say:—

"After making all allowances for all those modes of publicity for which there may be some justification, there remain many instances which can only be regarded as gravely and unnecessarily contravening the spirit of the notice of the G.M.C. The Association is convinced that in taking up an attitude of determined opposition to these undesirable journalistic methods the Association is acting in the best interests of the public as well as of the medical profession. The extension of the system can only lead to a competition for public notice in which the more scrupulous men would be left behind, to the detriment of the public who are ill-qualified to judge of the true worth of scientific opinions. The extension of the advertising habit among the profession in general would certainly destroy those traditions of dignity and self-respect which have helped to give the British medical profession its present high status, and would gravely undermine the amenities and harmonious working of medical practice. The Association, therefore, draws the attention of the profession to the danger of these objectionable methods, and insists upon the urgent need that every member of the profession who values its honour should offer a firm resistance to them. If only those whose reputation is mainly derived from newspapers allow their names and opinions to be quoted or to appear as those of 'the eminent' physician, surgeon, or specialist, the practice will die a natural death."

Locum-Tenents.

The following motion governing the conduct of a practitioner desiring to set up practice in the area in which he had acted as a locum-tenent was carried without discussion:—

> That as a locum-tenent is introduced in confidence to the practice of which he takes charge, it must be presumed on principles of common equity that he cannot without dishonour commence practice in the neighbourhood where he has acted unless with a written consent obtained either from the practitioner whose substitute he has been or from the legal representatives of this practitioner. There may, however, be circumstances, for example of lapse of time, which would make the strict application of this rule an unreasonable interference with the freedom of the practitioner who had acted as a locum-tenent. If any such plea for the relaxation of the rule in any individual case can be advanced the facts should be stated to the Central Ethical Committee, and the judgment of the Central Ethical Committee on the point should be accepted as final.

Blacklegging.

A discussion followed on a motion brought forward by Dr. M. W. Renton, on behalf of the Dartford division, arising out of certain practical difficulties experienced by the Kent branch, which were explained to the meeting by the branch secretary, Dr. E. A. Starling. The present regulation allowed a practitioner to apply for a post at a salary below the B.M.A. scale in spite of protests, to secure the appointment, and then to negotiate with his employers so that the salary was brought up to the minimum by means of addition or emolument. He would then be restored to his position in the profession, to the chagrin of loyal members who had withdrawn their applications. Dr. Langdon Down expressed his sympathy with the aim of the Kent branch, but did not consider it necessary to alter the ethical rules to attain that end. Rule V. was intended to apply to established posts already held, in order to give their occupiers an alternative to resignation. Any individual applying for a new post advertised at an inadequate salary should be dealt with under Rule VI. as a recalcitrant member. The Association had been passing through a transition period in the matter of salaries, and no final decision had yet been reached. Both he and the solicitor, Mr. W. E. Hempson, urged the meeting not to throw the ethical rules again into the melting-pot, nor to make an alteration without considering very carefully where it might lead. The motion was lost.

Alleged Abuses of Psycho-analysis.

Dr. A. Lyndon (Hindhead) formally proposed a motion:—

> That the Representative Body instruct the Council to consider certain practices alleged to be prevalent among some medical men practising psycho-analysis and to report.

Dr. J. A. Parry (Brighton), bringing forward examples of the practices referred to, said he wished it to be clearly understood that this was not an attack on psycho-analysis as such, but was the result of much careful consideration by the Sussex Branch Council for many months. Judges and journalists were discussing these things, and it behoved the medical profession to take some action lest it be forced on them from without. He asked for discreet investigation, not condemnation.

Dr. Langdon Down said that there were two ways in which a practitioner might be considered by others to fail in his practice. He might hold a judgment with which his fellows entirely disagreed, but this could only be made an offence if the whole question were considered and rules laid down as to what was right, or he might deliberately do things contrary to his judgment, which would be extremely hard to prove. The best means open to the profession for the propagation of truth were scientific meetings and the columns of the medical press. Where a medical practitioner committed an offence against the public the remedy lay in the hands of the offended party; it was no part of the profession's duty to act for him. The speaker doubted whether the matter were worth putting to the Council.

Dr. Hawthorne agreed that it was a case for the police or the General Medical Council, rather than for the British Medical Association, which was not a legal judicial authority.

Dr. C. E. Douglas (Fife) said that this was an important and very serious allegation, far too important and difficult for the Representative Body to deal with. The Council could receive evidence for and against, and give a considered report.

Dr. Bolam said that there might well be matters for the police or the General Medical Council in this investigation, and yet be a residuum that might be dealt with by the Association or by representations from the Association in other quarters. He suggested that the whole question should be referred to the Council for consideration; beyond that it would be hazardous to go.

Dr. Parry accepted this amendment.

Health Insurance Service.

The reports of the Non-Panel and National Health Insurance Acts Committees were considered and accepted.

Dr. H. G. Dain (Birmingham Central) referred to the work of the latter in preparing evidence for the Royal Commission, and in establishing a panel of some 500 ophthalmic surgeons willing to see insured patients under the new ophthalmic benefit scheme. During the year the public press had taken active notice of certain difficult cases in which the Ministry of Health had given judgment. The Committee had obtained remission of the unpaid part of the fine in one of these cases, and had laid down four definite principles which should hold in cases where the Minister had to give judgment. To these the Minister had agreed, only differing in some slight details as to their application. The Defence Trust Fund had increased to £73,000, and the Committee had decided that the interest from it should be used in defraying expenses. Before long they might be considering what amount could be considered a sufficient reserve; at present they hoped that all committees would continue their subscriptions.

Appeal to the High Court.

A considerable discussion followed on the motion of Dr. H. J. Milbank-Smith (Chichester, Worthing, and Horsham):—

> That it be an instruction to the Council that when consulting the divisions as regards any suggested amendments of or additions to the policy of the Association in reference to the National Health Insurance Acts, or extensions of the same, they include for consideration the following proposal—namely, that, in addition to the right now enjoyed of appeal to the courts on the ground of improper procedure, appeal to the High Court shall be legitimate against any penalty, other than removal from the panel, imposed upon a practitioner by the Minister.

Dr. Milbank-Smith referred to recent cases in which the finding of the Minister had been contrary to that of a committee appointed to consider the case carefully. Much distress and anxiety had been caused to the profession by the lack of any possibility of appeal. An appeal in the Harnett case had completely reversed the situation and enormously strengthened the position of the profession. There might be a better relationship with the Ministry now, but ministers changed and there was no security that this would continue.

Dr. L. J. Picton (Chester, Crewe) said that N.H. Insurance had set up a new relationship between the practitioner and his patient, introducing a third party in the contract. The Common Law of the land should be the factor to adjust differences; the judges themselves did not think this would be unconstitutional. The patient could appeal to Common Law, and if a panel patient did so the Minister withheld his decision until the case had been tried; the doctor had no such right of appeal.

Dr. Dain reminded the meeting that a joint conference representing the whole profession had already agreed on this principle, and asked that cases involving removal from the panel should be submitted to a purely medical tribunal, while cases involving a fine should have the right of appeal to the High Courts.

The motion was lost.

Disciplinary Action by the Minister of Health.

Dr. R. D. Mothersole (Bolton) proposed :—

> (1) That the Representative Body strongly protests against the action of the Minister of Health in penalising Dr. X. for an alleged offence of which the Committee of Inquiry had declared that Dr. X. was not guilty, and that the charge ought not to have been brought; and (2) that the Minister of Health be invited to state what are the functions of a Committee of Inquiry, and how far its findings are binding on himself.

Dr. Dain said that representations had already been made to the Minister of Health on this matter, and he had agreed that judgment of proficiency must be a subject for the General Medical Council alone. The aim of this resolution had already been accomplished.

Some discussion followed, in which Dr. Brackenbury said it would be the opposite of serviceable to reiterate this protest, and Dr. Wallace Henry pointed out that to pass to the next business would look as if the meeting did not approve of the protest. The motion was eventually withdrawn in favour of the motion proposed by Dr. R. Wallace Henry (Leicester and Rutland), and seconded by Dr. J. F. Walker (South Essex) :—

> That this meeting approves the action of the Insurance Acts Committee in protesting in the case of Dr. X., and welcomes the declaration of the Minister of Health that he accepts the principle put forward by the deputation.

Royal Commission on Insurance.

Mr. E. B. Turner questioned the action of the Council in submitting the memorandum to the Royal Commission without bringing it before the Representative Body as such. He was extremely jealous for the democratic constitution of the Association and the rights of the Representative Body in which he had held every office from representative to chairman.

Dr. Bolam replied that the representatives had entered cheerfully into the method by which the Council had tried to obtain the opinion of the whole profession, and in his opinion it would have been very foolish to let the dry bones of the constitution over-ride the circumstances. The Association had repeatedly disregarded its standing orders in the effort to ensure that there should be no vestige of suspicion that it was trying to put forward anything in the name of the profession when outsiders had had no voice in it. The proceeding was eminently calculated to get the opinion of the whole profession as far as possible.

The Chairman pointed out that the evidence was not given as that of the Representative Body, but as that of the Council of the B.M.A. after certain procedures which were clearly set out. The present time was the correct occasion for the Representative Body to approve or censure the action of its Council.

No motion was put, but the applause that greeted Dr. Bolam's statement, showed that the meeting was satisfied that the method was a proper and constitutional way of dealing with the occasion.

Dividends on Panel Prescriptions.

Dr. C. J. Kirk (Darlington) then proposed :—

> (1) That the action of the Coöperative Societies in allowing the prescriptions presented by patients under the National Health Insurance Acts, who are also members of the Coöperative Societies, to rank for dividend is entirely opposed to the spirit of the Acts. It is calculated to encourage malingering, to throw unnecessary work upon the practitioners administering the medical benefit, and to bring the work of the Insurance Acts into disrepute. (2) That the Council be instructed to press the Ministry of Health to remove this abuse of the provisions of the National Health Insurance Acts.

On the suggestion of Dr. Dain, it was resolved :—

> That the motion be referred to the Council for investigation as to the extent of the practice.

Election of Council.

During the course of the day the unopposed return of the following 12 members to Council was announced : Dr. G. B. Hillman, Dr. I. W. Johnson, Dr. J. W. Bone, Dr. T. Ridley Bailey, Mr. E. B. Turner, Dr. W. Paterson, Dr. C. E. S. Flemming, Dr. S. Morton Mackenzie, Dr. C. E. Douglas, Dr. J. G. McCutcheon, Dr. John Mills, and Dr. J. Singleton Darling.

SATURDAY, JULY 18TH.

Membership of the B.M.A.

In presenting the report of the Organisation Committee, Dr. S. Morton Mackenzie said that the membership now totalled 29,680, a figure 3000 higher than ever before. He did not believe that the increase was a " flash in the pan," but it could not be expected to continue at that rate. They were particularly anxious now to do more for the young practitioner. The establishment of a scale of remuneration had placed them in the position of asking these men to give up posts without offering any help.

Locum Bureaus.

One way of helping them was by the foundation of a locum bureau, which was a real need in the provinces. Already several such local bureaus were in existence, but at present their position was unregularised. Legally the Association could not undertake such an activity, but it was proposed to form a private limited liability company in which the A shares, conveying voting power, would be held by officials and officers of the B.M.A., and the annual meeting of the company would be held during the session of the Representative Body.

A number of members asked questions, and discussed the legality and details of the proposed scheme.

Mr. Bishop Harman urged the meeting to express its opinion on the general principle and leave the details to the Council, who might be trusted to take every legal and financial precaution. Delay was dangerous as such bureaus were constantly being formed, and the more there were the greater the difficulty of coördination.

After some discussion as to the advisability of giving preferential treatment to B.M.A. members, the principle was approved.

Individual Medical Defence.

Dr. Morton Mackenzie, introducing a resolution authorising the Council to prepare a draft scheme and ascertain the number of members who would join in it, said that the discussions at Portsmouth and Bradford had made the Committee realise that there was still a very considerable minority that desired the Association to undertake the legal defence of its members. The Committee had, therefore, persuaded the Council to allow a thorough investigation of the matter, financially and historically. The history of the question had been written by Miss Lawrence, the intelligence officer, and showed that the argument had been going on for 50 years, and that the Council had repeatedly allowed the matter to slide even when the Representative Body had passed resolutions in favour of it.

Dr. Mackenzie said he thought he could shorten discussion by laying down certain propositions. First, he thought they were all agreed that if there were no existing defence societies it was a work the Association ought to undertake; secondly, they were quite agreed that the Association could not legally undertake the work under its existing articles and memorandum; thirdly, at the moment any form of coöperation with the existing societies was quite out of the question. He had held the opinion that the true solution of the question was to do it in coöperation with the existing societies, but he was sorry to say that neither of these societies had seen their way to accept the overtures.

The possibilities before the Association were: (1) Full medical defence for all members, either in conjunction with or in opposition to the existing societies. This he thought was not possible because very many members were quite satisfied with the societies. (2) Optional full defence for those members who wished for it. (3) Partial medical defence—e.g., every legal help given up to the door of the court and then no more, or meeting those expenses which were not paid by existing societies. (4) The establishment of a legal bureau at the offices for advice and help. In his opinion (2) was the only solution; it would satisfy those members who were agitating for B.M.A. defence without upsetting those who preferred to remain as they were. The disadvantages were few; there would be no reserve fund at first, but the new company would have the backing of the Association, and the brains in the B.M.A. office were quite as competent to manage the affair as any in the existing societies. It would require 6500 members to make its inauguration a sound financial proposition.

A motion from Guildford impugning the Council for bringing up the subject after the Representative Body had voted against it was rejected, but a lengthy discussion followed the amendment by Cardiff:—

That as the matter of individual medical defence is being competently dealt with by various existing bodies, and as it does not appear that the Association could conduct medical defence in any cheaper or better manner, and as the provision of individual medical defence is not within the present powers of the Association, this meeting is of the opinion that the matter should be dropped, and that the expense of the proposed referendum of the profession be not incurred; but that the Association should bring to the notice of all practitioners, especially those recently qualified, the urgent necessity of joining one of the medical defence bodies.

Dr. Peter Macdonald (York) and others raised the question of indefensible conduct and the loss of prestige to the Association if it found itself compelled to defend such a case.

Mr. McAdam Eccles (London) and Dr. S. N. Scott (Plymouth) spoke of the difficulty of persuading men to join the Association when their immediate question as to the provision of defence had to be answered in the negative.

Several members, including Mr. E. B. Turner and Dr. J. C. Matthews, voiced the impracticability of the scheme. The financial position would be most insecure at first, the new company would be unable to meet a large case; it would be most unfortunate for the Association to have to defend a man brought before the General Medical Council, and all B.M.A. members would have to leave the Council while such a case was being tried.

Dr. D. Lawson urged that the cobbler should stick to his last; he was not so optimistic as to accept the estimate of the ability of the B.M.A. staff, and its funds had not been accumulated to squander on speculation.

Dr. J. Neal (Hendon) said that the requirements of the profession were already fully met, and this doubtful experiment offered no advantage to its members. He denied that the existing societies had ever been asked to coöperate; they had only been asked to grant financial concessions, at their own expense, to members of the B.M.A.

Dr. J. F. Walker (Essex) thought that this dangerous weapon would be looked upon as an attempt on the part of the B.M.A. to entrench themselves behind their prerogatives to the detriment of the public and might well prove to be another horse of Troy.

Other members, including Dr. C. Sanders and Dr. C. E. Douglas (Fife), pointed out that the resolution only asked the Council to obtain information and report in order to show what the demand was and how far it might be practicable. If the scheme came into being it would only be by the support of the younger men; the seniors were loyal to their own societies and were not going to let them down, but times were changing and young men were coming on; this might be the step of the future.

Dr. Christine Murrell (London) said that if the new company were to be closely associated with the B.M.A., the practical difficulties would be very great and might be disastrous; if it were to be but loosely connected it would be equivalent to setting up a third society for which there was no particular need. There was a definite advantage to the individual in being able to get the little difficulties of practice redressed by a protection society without having to make it known to the professional and scientific association.

Dr. Dain believed that individual medical defence would mean loss of prestige; the Association had always maintained that anything it did must be in the interest of the public or else it could not be in the real interest of the profession. He thought the solution lay in real coöperation with the existing societies, which need not necessarily mean preferential treatment.

Dr. J. S. Manson (Warrington) suggested that the local division might decide whether any particular case should be taken up by the B.M.A. or not, but as Dr. Hawthorne and Dr. E. E. Brierley pointed out, this would place the divisions in an invidious position and might lead to conflict between the local and central authority.

Dr. E. R. Fothergill (Brighton) spoke of the difficulty of finding a suitable firm of solicitors, and said that the only real coöperation was for the B.M.A. to increase its subscription to £4 and offer to pay the subscription to any defence society the member chose.

Mr. Bishop Harman said that there was a growing involvement of medical defence with general propositions; it was no longer possible to leave defence of the individual to one society and of the profession to another. In the Harnett case the defence of the individuals had been the defence not only of the profession but of the public. Already the defence societies were giving advice on general medical matters. Coöperation was desirable, but coöperation could not be attained until the B.M.A. made up its mind what it was going to do. The future lay with those who had closest touch with the new practitioners. He begged the meeting to let the Council find out once and for all what was the volume of the demand which had so frequently made itself heard in the history of the Association.

The amendment by Cardiff was carried, on a roll-call vote of 97 to 72, and the principle of individual medical defence was thus again rejected.

Inquiries and Badges.

In moving the adoption of the Supplementary Report under Organisation, Dr. Morton Mackenzie said that the questions answered at the offices were increasing in multitude and variety; in addition to problems of practice and lodgings, they were asked how to open a banking account and how to get married, and, more particularly, about post-graduate work, which must clearly be the next activity of the Association. The overseas branches were in a satisfactory condition. New members of the Standing Committees were wanted. It was proposed that branch and division chairmen and secretaries should have a standard badge to enhance the dignity of their office.

Dr. C. G. H. Morse described a series of successful post-graduate courses in Bournemouth, and hoped the B.M.A. would not look on London as the only place for post-graduate work.

Dr. J. Stevens proposed that miniature badges should also be prepared, that ex-chairmen and secretaries might keep as permanent mementoes of their work.

Parliamentary Fund.

Dr. E. K. Le Fleming (Dorset and W. Hants) presented the report of the Parliamentary Committee and emphasised the fact that the Association had no political bias, but required that those who received its support should subscribe to the broad principles of policy laid down by the Representative Body. So long as the Labour Party had as a plank in its platform the State Medical Service and State aid for hospitals they could not assist its candidates. The position of the profession in Parliament was much more satisfactory than hitherto. The aim of the Committee was that the requirements of the profession should be clearly stated in the House, but the state of the Parliamentary Fund was still very unsatisfactory.

Investiture.

During the meeting the Chairman was invested with the new badge of office, bought in honour of the twenty-first meeting of the Representative Body, by Dr. W. Douglas, "the father of the Representative Body," supported by Dr. Milner Moore, a member of the Association since 1869.

(*To be continued.*)

CONVENTION OF ENGLISH-SPEAKING OPHTHALMOLOGICAL SOCIETIES.

LONDON, JULY 14TH–17TH.

(*Continued from p. 150.*)

ON the evening of Wednesday, July 15th, there was a very large gathering of members of the Convention to hear a symposium on the subject of the

EVOLUTION OF BINOCULAR VISION,

the chair being occupied by Mr. Treacher Collins, the President.

Prof. Elliot Smith said there were certain aspects of this problem upon which anatomists could throw a certain amount of light, or at least they could define certain issues which other speakers could more fully interpret. He considered that the problem of binocular vision was of the very essence of the question of human evolution, as the cultivation of vision and the increased reliance on it for guidance was the fundamental fact which brought about the evolution of the Primates and led to those distinctive qualities which differentiated man from other living creatures. Man's ancestors were certainly the first creatures to see the world in the sense properly understood. Such vision resulted in the ability to perform skilled movements and to acquire by experimentation a knowledge of the world and of the events-taking place in it, the knowledge which placed man in his position of supremacy. Thus, the problem was not merely that of the functional association of the two eyes in vision, but a study of the factor which constituted the primary stimulus to the emergence of the distinctive qualities possessed by man. The student had first to try and trace what series of animals could throw light on this gradual development. Fortunately, in the case of the Primates there survived—in many cases from the Tertiary geologic period—a series of creatures which had escaped the devastating effects of extreme specialisation, and so enabled a study to be made of the phases through which man's ancestry passed. The Primates came into existence in North America, near Wyoming, before the beginning of the Tertiary period; there they separated from the group of insectivorous animals, which had been studied so well by Mr. Le Gros Clark in Borneo, who specially examined the structure of the eye and retinæ, the cerebral cortex, and the oculo-motor nucleus. Shortly before the beginning of the Tertiary period the lemurs came into existence, and in one particular class smell began to be replaced by vision as a guiding sense. Primitive monkeys came into existence in the middle of the Eocene period, reaching Europe from South America, and they split up into tailed monkeys and the higher group of anthropoids. It was not until after that period that the giant anthropoids came into being. The nearest remains of the human family belonged to the Pleistocene period, but there still remained a gap which was unspanned. The most important class of animals for this study was the tarseus, as it had survived from the beginning of the Eocene period with practically no change. There was a shrinking and flattening of the nose to allow the eyes to come to the front of the face, so that the creature could look forward, and the visual fields overlapped almost as much as they did in the case of monkeys and in man. It was possible to demonstrate the fact that the ora striata reached its maximum size even in the most primitive monkeys, so that as the brain was much smaller in them than in the higher Primates, the visual cortex in them was proportionately great. Using this method, the speaker was able some years ago to map out, without histological technique, the distribution of the cortical areas in the series of animals represented in a diagram he exhibited, commencing with the jumping shrew. The primitive animal was guided by its sense of smell, but in its arboreal cousin smell was reduced and place was given to areas for vision, hearing, touch, &c. It was the development of the visual cortex which led to the emergence of the tarsoids, and in these there was an enormous reduction in the cortical area assigned to the olfactory sense and an increase in that subserving sight. He made this inquiry 15 years ago, and since then Mr. Le Gros Clark had shown the same thing by histological methods. Comparing the tarseus with the marmoset, a profound transformation in the brain structure was noted. Not only was the brain of the latter much the bigger, but there was a great expansion of areas allocated to sight, hearing, touch, and the pre-frontal region generally. All this made for increased precision of movement, and especially of finer movements. Equally certainly a very profound accompaniment of delicate intensive manipulations was the acquisition and development of binocular vision.

A striking pre-binocular vision stage was illustrated in the case of the chameleon, for this animal could look forwards with one eye and backwards with the other, and it used its eyes for fixing an object in much the same way as it shot out its tongue to seize its prey. The actual fixing of an object by the eyes occupied some minutes, the concentration being, doubtless, on the muscular act rather than on the object seen. It was this linked separate movement of convergence which had developed in mammals. Dr. Wilfred Harris had shown that the optic tracts of all vertebrates other than mammals could cross, but a certain number of fibres remained uncrossed. In some animals there was a reduction in the size of the snout, which allowed the eyes to move forwards, a prior necessity before stereoscopic vision could be acquired. Mr. Le Gros Clark had examined the retinæ of both living and dead tarseus, but was unable to find anything resembling a macula, either by ophthalmoscopic examination, by gross anatomy, or by histological methods. But though the eyes of tarseus looked forward and it had developed its ora serrata to a greater extent than had the lemur, and though its visual fields overlapped, it yet had not acquired full powers of stereoscopic vision, nor of guiding its hand movements as the monkey could, nor of carrying out a range of conjugate movements. There was evidence, however, that this animal felt the need of these accomplishments, and in obedience to that need it acquired the ability to so move its head that it could and did look backwards, as shown by an actual photograph. Research during 40 years had shown that it was the great pre-frontal area of the brain which was concerned with controlling these more complex conjugate movements which were distinctive of the apes and man. A true macula lutea was found only in the latter two species. In marsupials there was a small region in front of the motor area which controlled movements in only one eye. He showed slides of micro-photographs demonstrating that the eyes underwent transition from lemur to tarseus and then to monkey.

Sir Frederick Mott referred to the thesis he propounded in his Bowman lecture of 20 years ago, when he dealt with the evolution of binocular vision coincidently with that of the visual cortex. The conclusions then expressed had been confirmed, and he had not had the opportunity of carrying his research further. He exhibited slides showing that the lunate sulcus seen in all anthropoids was sometimes to be observed in man also. With the rise in the animal scale the peri-striate area of the occipital lobe was found to be increased, and coincidently there was a greater development of the frontal region of the brain. It had been found by Prof. Watson, of Baltimore, that a baby could fix a light soon after birth, but not until the 130th day did it acquire associated hand movements. It was found that in the full-term fœtus there was a myelination of the optic radiations, and hence it was argued that this region was instrumental in fixing the light. Sir Frederick Mott showed that all our visual experiences were associated with tactile perceptual ones, and exhibited a number of slides illustrative of the work which Prof. Sherrington and he did together. Closely associated with the area concerned with the conjugate movements of the eyes was that regulating movements of the eyelids. His conclusion was that the frontal region of the brain was that concerned with attention, and especially with that associated with binocular vision.

Prof. S. E. Whitnall (McGill) explained that his interest in this problem had been mainly with the movements of the eye muscles during the gradual transition of the eyes from the side of the head to the front of the head. He first pointed out how little animals, especially mammals, moved their eyes in order to see. Lemurs and all animals below them moved their heads instead of their eyes, and human beings moved their heads in order to see to a greater extent than was usually realised. This was appreciated in the light of the sense of inconvenience when one suffered from a stiff neck. The more an animal felt the need to increase its visual field, the more developed its muscles became. But one could find that some means were taken to compensate for this lack of development of muscles. If the eye was not moved to increase the visual field, the orbit could be moved, thus increasing the avenues of approach to the retina, and in herbivora there was an elongated pupil with the same purpose. Throughout all the vertebrate series there were the same four recti and two obliques. Prof. Whitnall showed by a series of diagrams the changes which occurred in the muscles of the site pari passu with the gradual swinging of the visual axes from the side to the front of the head, the angle subtended by the visual and orbital axes varying from 27° to 80°. He dealt in much detail with the change seen in each pair of muscles, and showed illustrations from Lindsay Johnson's atlas of the visual axes in various mammals.

Sir Arthur Keith, in view of the full contributions of his predecessors in this discussion, confined his attention almost solely to the chief modifications which had been gone through by the orbit and the skull in the evolution of binocular vision. Presumably, man began to take on a recognisable human form in the Miocene period, but his ocular outfit existed long before—namely, in the Eocene period—and he preferred for it the name "bifoveate." Even the marmoset had this. The progeny of the bifoveate stock had fared very differently in their evolutionary progress. Some had retained their ancient characters, others, such as man, had shed them. Between them was a series of intermediate forms, seen in living Primates, representing stages in evolutionary progress. By a deft use of those intermediate forms Prof. Elliot Smith had been able to build up a reliable evolutionary history of man's vision and of those parts of the brain which were concerned with that faculty. One of the greatest services rendered to anatomy was Prof. Elliot Smith's clear proof that the evolution of bifoveate vision was the result of sight ousting smell as the dominant sense. Sir Arthur Keith did not consider that the swinging forward of the eyes so that their axes became parallel had anything to do with the reduction in size of jaws, nor that bifoveate vision was a necessary result of arboreal life; he thought it was closely linked with the mode of climbing, and mode of locomotion seemed to have been a dominant factor in the evolution of the true Primates. All bifoveate Primates were jumpers, and they must be able to judge the distance of the branch they wished to reach. The golfer's axiom "Keep your eye on the ball" had a much older counterpart in the jungle, "Keep your eye on the branch." Twenty-four years ago the late Dr. Lindsay Johnson showed that though monkeys, anthropoid apes, and man had the same form of eye and retina, the same outfit of ocular and orbital muscles, these creatures differed widely in the degree and kind of their eye movements. In ordinary monkeys head and eyes moved together, there was but little power of lateral movement of the eyes. In the great anthropoid apes conjugate movements were free and frequent, convergence could be sustained only during short spells. It was clear that man's visual superiority lay not in the kind of eye with which he had been provided, but in the brain which had grown up behind the eyes. No one, he said, who had watched the gradual dawn of perfect vision between birth and childhood could doubt the truth of evolution; the facts deduced that evening could only be explained by supposing that man had been evolved from a very humble and primitive simian ancestry. But we remained still in the dark as to the evolutionary machinery which had transformed the visual world as seen by the marmoset into that seen by man. When this machinery was explained it must cover all the structural elements as they developed in the body of the embryo and of the fœtus. When it could be explained how man came by his vision, then the most difficult part of the problem of evolution would have been solved.

On Thursday, July 16th, Sir John Parsons delivered the Bowman lecture, which appeared at length in our last issue.

On the morning of Friday, July 17th, the session combined to debate on the

MICROSCOPY OF THE LIVING EYE,

the President occupying the chair.

The Cornea.—Dr. Gordon Byers (Montreal) dealt with the cornea, remarking that because of its accessibility and the transparency of its refractive media, the eye early became a field for study by what had come to be called the "direct" method of pathological examination. With increasing accuracy and fullness the changes noted were isolated and described as the objective symptoms or signs of the clinical pictures. But though the direct method did evolve aids of great value, beginning with the introduction of focal illumination by Himley over 100 years ago, limits to its effectiveness were imposed by difficulties of illumination which seemed at the time to be insuperable. The value, he said, of the new method lay rather in its disclosing changes collectively, and in their topographic relations, a service of which the pathologist stood in need. For him it made significant many details which merely as scattered findings were without meaning. To the clinician the method gave fresh opportunities to add to the number and the qualities of his clinical pictures. Pathological changes in the cornea were observable with a special fullness and distinctness by the new method, because of the variety of illumination which focal structural differentiation made available for disclosure. Still, the revelations of the slit-lamp would probably be less novel in the cornea than it would in other components of the organ. He thought that betterment would consist rather in the addition of a wealth of detail and a truer perspective to details already established.

The Vitreous.—Dr. Arthur Bedell (Albany, New York) said the slit-lamp offered a method for the more careful study of vitreous detail than had hitherto been available. The vitreous, when examined by this method, showed innumerable variations in the definition of the folds of the frame-work and the consistency of the fibres in health. In disease the changed framework might consist in the massing of fibres and liquefaction and absorption of structures, and in pigmentation. He considered that no case of penetrating injury had been properly investigated until the slit-lamp had been skilfully used; and prognosis in such cases was never exact until such demonstration revealed the presence or absence of tension fibres which might be a cause of subsequent detachment. He gave a series of hints as to the use of the instru-

Investiture.

During the meeting the Chairman was invested with the new badge of office, bought in honour of the twenty-first meeting of the Representative Body, by Dr. W. Douglas, "the father of the Representative Body," supported by Dr. Milner Moore, a member of the Association since 1869.

CONVENTION OF ENGLISH-SPEAKING OPHTHALMOLOGICAL SOCIETIES.

LONDON, JULY 14TH–17TH.

(*Continued from p. 160.*)

ON the evening of Wednesday, July 15th, there was a very large gathering of members of the Convention to hear a symposium on the subject of the

EVOLUTION OF BINOCULAR VISION,

the chair being occupied by Mr. Treacher Collins, the President.

Prof. Elliot Smith said there were certain aspects of this problem upon which anatomists could throw a certain amount of light, or at least they could define certain issues which other speakers could more fully interpret. He considered that the problem of binocular vision was of the very essence of the question of human evolution, as the cultivation of vision and the increased reliance on it for guidance was the fundamental fact which brought about the evolution of the Primates and led to those distinctive qualities which differentiated man from other living creatures. Man's ancestors were certainly the first creatures to see the world in the sense properly understood. Such vision resulted in the ability to perform skilled movements and to acquire by experimentation a knowledge of the world and of the events taking place in it, the knowledge which placed man in his position of supremacy. Thus, the problem was not merely that of the functional association of the two eyes in vision, but a study of the factor which constituted the primary stimulus to the emergence of the distinctive qualities possessed by man. The student had first to try and trace what series of animals could throw light on this gradual development. Fortunately, in the case of the Primates there survived—in many cases from the Tertiary geologic period—a series of creatures which had escaped the devastating effects of extreme specialisation, and so enabled a study to be made of the phases through which man's ancestry passed. The Primates came into existence in North America, near Wyoming, before the beginning of the Tertiary period; there they separated from the group of insectivorous animals, which had been studied so well by Mr. Le Gros Clark in Borneo, who specially examined the structure of the eye and retinæ, the cerebral cortex, and the oculo-motor nucleus. Shortly before the beginning of the Tertiary period the lemurs came into existence, and in one particular class smell began to be replaced by vision as a guiding sense. Primitive monkeys came into existence in the middle of the Eocene period, reaching Europe from South America, and they split up into tailed monkeys and the higher group of anthropoids. It was not until after that period that the giant anthropoids came into being. The nearest remains of the human family belonged to the Pleistocene period, but there still remained a gap which was unspanned. The most important class of animals for this study was the tarseus, as it had survived from the beginning of the Eocene period with practically no change. There was a shrinking and flattening of the nose to allow the eyes to come to the front of the face, so that the creature could look forward, and the visual fields overlapped almost as much as they did in the case of monkeys and in man. It was possible to demonstrate the fact that the ora striata reached its maximum size even in the most primitive monkeys, so that as the brain was much smaller in them than in the higher Primates, the visual cortex in them was proportionately great. Using this method, the speaker was able some years ago to map out, without histological technique, the distribution of the cortical areas in the series of animals represented in a diagram he exhibited, commencing with the jumping shrew. The primitive animal was guided by its sense of smell, but in its arboreal cousin smell was reduced and place was given to areas for vision, hearing, touch, &c. It was the development of the visual cortex which led to the emergence of the tarsoids, and in these there was an enormous reduction in the cortical area assigned to the olfactory sense and an increase in that subserving sight. He made this inquiry 15 years ago, and since then Mr. Le Gros Clark had shown the same thing by histological methods. Comparing the tarseus with the marmoset, a profound transformation in the brain structure was noted. Not only was the brain of the latter much the bigger, but there was a great expansion of areas allocated to sight, hearing, touch, and the pre-frontal region generally. All this made for increased precision of movement, and especially of finer movements. Equally certainly a very profound accompaniment of delicate intensive manipulations was the acquisition and development of binocular vision.

A striking pre-binocular vision stage was illustrated in the case of the chameleon, for this animal could look forwards with one eye and backwards with the other, and it used its eyes for fixing an object in much the same way as it shot out its tongue to seize its prey. The actual fixing of an object by the eyes occupied some minutes, the concentration being, doubtless, on the muscular act rather than on the object seen. It was this linked separate movement of convergence which had developed in mammals. Dr. Wilfred Harris had shown that the optic tracts of all vertebrates other than mammals could cross, but a certain number of fibres remained uncrossed. In some animals there was a reduction in the size of the snout, which allowed the eyes to move forwards, a prior necessity before stereoscopic vision could be acquired. Mr. Le Gros Clark had examined the retinæ of both living and dead tarseus, but was unable to find anything resembling a macula, either by ophthalmoscopic examination, by gross anatomy, or by histological methods. But though the eyes of tarseus looked forward and it had developed its ora serrata to a greater extent than had the lemur, and though its visual fields overlapped, it yet had not acquired full powers of stereoscopic vision, nor of guiding its hand movements as the monkey could, nor of carrying out a range of conjugate movements. There was evidence, however, that this animal felt the need of these accomplishments, and in obedience to that need it acquired the ability to so move its head that it could and did look backwards, as shown by an actual photograph. Research during 40 years had shown that it was the great pre-frontal area of the brain which was concerned with controlling these more complex conjugate movements which were distinctive of the apes and man. He showed slides of micro-photographs demonstrating that the eyes underwent transition from lemur to tarseus and then to monkey.

Sir Frederick Mott referred to the thesis he propounded in his Bowman lecture of 20 years ago, when he dealt with the evolution of binocular vision coincidently with that of the visual cortex. The conclusions then expressed had been confirmed, and he had not had the opportunity of carrying his research further. He exhibited slides showing that the lunate sulcus seen in all anthropoids was sometimes to be observed in man also. With the rise in the animal scale the peri-striate area of the occipital lobe was found to be increased, and coincidently there was a greater development of the frontal region of the brain. It had been found by Prof. Watson, of Baltimore, that a baby could fix a light soon after birth, but not until the 130th day did it acquire associated hand movements. It was found that in the full-term fœtus there was a myelination of the optic radiations, and hence it was argued that this region was instrumental in fixing the light. Sir Frederick Mott showed that all our visual experiences were associated with tactile perceptual ones, and exhibited a number of slides illustrative of the work which Prof. Sherrington and he did together. Closely associated with the area concerned with the conjugate movements of the eyes was that regulating movements of the eyelids. His conclusion was that the frontal region of the brain was that concerned with attention, and especially with that associated with binocular vision.

Prof. S. E. Whitnall (McGill) explained that his interest in this problem had been mainly with the movements of the eye muscles during the gradual transition of the eyes from the side of the head to the front of the head. He first pointed out how little animals, especially mammals, moved their eyes in order to see. Lemurs and all animals below them moved their heads instead of their eyes, and human beings moved their heads in order to see to a greater extent than was usually realised. This was appreciated in the light of the sense of inconvenience when one suffered from a stiff neck. The more an animal felt the need to increase its visual field, the more developed its muscles became. But one could find that some means were taken to compensate for this lack of development of muscles. If the eye was not moved to increase the visual field, the orbit could be moved, thus increasing the avenues of approach to the retina, and in herbivora there was an elongated pupil with the same purpose. Throughout all the vertebrate series there were the same four recti and two obliques. Prof. Whitnall showed by a series of diagrams the changes which occurred in the muscles of the site pari passu with the gradual swinging of the visual axes from the side to the front of the head, the angle subtended by the visual and orbital axes varying from 27° to 80°. He dealt in much detail with the change seen in each pair of muscles, and showed illustrations from Lindsay Johnson's atlas of the visual axes in various mammals.

Sir Arthur Keith, in view of the full contributions of his predecessors in this discussion, confined his attention almost solely to the chief modifications which had been gone through by the orbit and the skull in the evolution of binocular vision. Presumably, man began to take on a recognisable human form in the Miocene period, but his ocular outfit existed long before—namely, in the Eocene period—and he preferred for it the name "bifoveate." Even the marmoset had this. The progeny of the bifoveate stock had fared very differently in their evolutionary progress. Some had retained their ancient characters, others, such as man, had shed them. Between them was a series of intermediate forms, seen in living Primates, representing stages in evolutionary progress. By a deft use of these intermediate forms Prof. Elliot Smith had been able to build up a reliable evolutionary history of man's vision and of those parts of the brain which were concerned with that faculty. One of the greatest services rendered to anatomy was Prof. Elliot Smith's clear proof that the evolution of bifoveate vision was the result of sight ousting smell as the dominant sense. Sir Arthur Keith did not consider that the swinging forward of the eyes so that their axes became parallel had anything to do with the reduction in size of jaws, nor that bifoveate vision was a necessary result of arboreal life; he thought it was closely linked with the mode of climbing, and mode of locomotion seemed to have been a dominant factor in the evolution of the true Primates. All bifoveate Primates were jumpers, and they must be able to judge the distance of the branch they wished to reach. The golfer's axiom "Keep your eye on the ball" had a much older counterpart in the jungle, "Keep your eye on the branch." Twenty-four years ago the late Dr. Lindsay Johnson showed that though monkeys, anthropoid apes, and man had the same form of eye and retina, the same outfit of ocular and orbital muscles, these creatures differed widely in the degree and kind of their eye movements. In ordinary monkeys head and eyes moved together, there was but little power of lateral movement of the eyes. In the great anthropoid apes conjugate movements were free and frequent, convergence could be sustained only during short spells. It was clear that man's visual superiority lay not in the kind of eye with which he had been provided, but in the brain which had grown up behind the eyes. No one, he said, who had watched the gradual dawn of perfect vision between birth and childhood could doubt the truth of evolution; the facts deduced that evening could only be explained by supposing that man had been evolved from a very humble and primitive simian ancestry. But we remained still in the dark as to the evolutionary machinery which had transformed the visual world as seen by the marmoset into that seen by man. When this machinery was explained it must cover all the structural elements as they developed in the body of the embryo and of the fœtus. When it could be explained how man came by his vision, then the most difficult part of the problem of evolution would have been solved.

On Thursday, July 10th, Sir John Parsons delivered the Bowman lecture, which appeared at length in our last issue.

On the morning of Friday, July 17th, the session combined to debate on the

MICROSCOPY OF THE LIVING EYE,

the President occupying the chair.

The Cornea.—Dr. Gordon Byers (Montreal) dealt with the cornea, remarking that because of its accessibility and the transparency of its refractive media, the eye early became a field for study by what had come to be called the "direct" method of pathological examination. With increasing accuracy and fullness the changes noted were isolated and described as the objective symptoms or signs of the clinical pictures. But though the direct method did evolve aids of great value, beginning with the introduction of focal illumination by Himley over 100 years ago, limits to its effectiveness were imposed by difficulties of illumination which seemed at the time to be insuperable. The value, he said, of the new method lay rather in its disclosing changes collectively, and in their topographic relations, a service of which the pathologist stood in need. For him it made significant many details which merely as scattered findings were without meaning. To the clinician the method gave fresh opportunities to add to the number and the qualities of his clinical pictures. Pathological changes in the cornea were observable with a special fullness and distinctness by the new method, because of the variety of illumination which focal structural differentiation made available for disclosure. Still, the revelations of the slit-lamp would probably be less novel in the cornea than it would in other components of the organ. He thought that betterment would consist rather in the addition of a wealth of detail and a truer perspective to details already established.

The Vitreous.—Dr. Arthur Bedell (Albany, New York) said the slit-lamp offered a method for the more careful study of vitreous detail than had hitherto been available. The vitreous, when examined by this method, showed innumerable variations in the definition of the folds of the frame-work and the consistency of the fibres in health. In disease the changed framework might consist in the massing of fibres and liquefaction and absorption of structures, and in pigmentation. He considered that no case of penetrating injury had been properly investigated until the slit-lamp had been skilfully used; and prognosis in such cases was never exact until such demonstration revealed the presence or absence of tension fibres which might be a cause of subsequent detachment. He gave a series of hints as to the use of the instru-

ment, and showed slides illustrative of the appearances seen in uveitis, retinitis proliferans, detachment of retina, asteroid hyalitis, and traumatic vitreous. In connexion with cataract extraction, Dr. Bedell said there was always a prolapse of vitreous after this operation if the posterior capsule was opened.

The Lens.—This part of the subject was dealt with by Mr. T. Harrison Butler (Birmingham). He said the lens was suspended in the eye like the hub of a bicycle and was completely surrounded by aqueous. The retro-lental space was a cleft filled with aqueous, and it disappeared in cases of degeneration of the vitreous. After the removal of cataract in the young the retro-lental space was greatly enlarged. He said that in cases of congenital dislocation of the lens the zonule might be complete, rudimentary, or absent altogether. When the lens was forcibly dislocated, the zonular lamella might peel off with the fibres of the suspensory ligament, which were not then found attached to the lens. He showed drawings illustrating detachment in lens dislocation, in glass-blower's cataract, and in an example of a shrunken lens. The lens sutures were known to constitute the sites of various kinds of cataract. The lens shagreen he regarded as due to the intimate structure of the capsule itself. He showed that an abnormal growth of the lens zones caused central cataracts, and to the varied forms of zonular or lamellar cataract. He suggested that the varied curves associated with appropriate refractive indices were so balanced that chromatic aberration was corrected.

Mr. Basil Graves dealt chiefly with the optics of these new instruments, and had a good many hints to impart on their successful use. His contribution was chiefly an epidiascope demonstration.

Miss Ida Mann spoke on the embryology of the lens and the correlation of it with slit-lamp appearances. In the first stage shown the lens was present only as an open pit in the surface ectoderm. At this stage could be seen the beginnings of the free cells, which were later seen in the cavity of the lens vesicle, the persistence of which Vogt considered was the cause of anterior axial embryonic cataract. But examination of this and succeeding stages to full term made this unlikely, as the opacities described as occurring in the adult lens were in the neighbourhood of the anterior Y-suture, while the potential cavity of the lens vesicle was immediately under the anterior lens epithelium.

Other participants in the discussion were Mr. Charles Goulden, Mr. Inglis Pollock, Mr. Gray Clegg, Dr. Feingold, Dr. Zentmayer, Dr. Finoff, Dr. McLean, and the President. The openers replied.

Reading of Papers.

At the afternoon session on Friday papers were read covering a wide variety of subjects. Mr. Leslie Paton and Miss Mann presented an elaborate thesis on the

Development of the Oculo-Motor Nuclei

and its bearing on the Argyll Robertson pupil reaction. They said that the break in the reflex arc which brought about the Argyll Robertson pupil probably occurred in the secondary intercalated neurone, which had its cell of origin in the anterior corpus quadrigeminum and whose axone passed down and probably bifurcated so as to link up with the third nerve nuclei on both sides. If the Edinger Westphal nuclei were concerned in the innervation of the sphincter pupillæ it was probable that the light reflex fibres were non-myelinated fibres running through the central grey matter straight to the neighbourhood of the Edinger Westphal nuclei. But Magitot contended that the Edinger Westphal nuclei could not be concerned with the control of the sphincter iridis, because in the human fœtus neither they nor any of the other anterior accessory nuclei of the third were developed at a time when the light reflex was already existent. That authority had seen the light reflex in a child which was born at the end of the fifth month, whereas the nuclei in question did not appear until the seventh month of intrauterine life. Mr. Paton suggested a reinvestigation of the embryology of the third nerve nucleus and its accessory nuclei, as that might throw light on this difficult question. A result of the examination of human embryos at various stages undertaken by one of the authors of this paper was that it seemed that the differentiation of the third nerve nucleus into its component parts commenced at a comparatively early stage, being well advanced before the end of the fifth month. Reference was made to the work of Kappers, and Mr. Paton said it could be shown that in human embryos the median nucleus appeared early, before the accessory nucleus, at a time when the swinging round of the eyes from the sides to the front of the head was taking place, while the appearance of the accessory nucleus was delayed until the first signs of differentiation of the margin of the optic cup to form an irido-ciliary region. In fœtuses of three and a half to four months the typical small cells of the accessory nuclei could be recognised, the anterior layer of the ectodermal part of the iris at the same time giving rise to the muscle-cells of the sphincter pupillæ. Thus, in both phylogeny and ontogeny the appearance of the median nucleus was associated with the possibility of convergence, and that of the Edinger Westphal nucleus with the possibility of a light reaction.

Glioma Retinæ.

Dr. J. Van der Hœve (Leiden) showed photographs of metastases of glioma retinæ in various parts of the head of a child after binocular enucleation, with the result of causing a massive disfigurement of the whole head and face. Exenteration of the orbit showed an optic nerve three to four times the normal size. The enlargement of the optic foramen he regarded as of serious prognostic import. In unilateral glaucoma the eye should be enucleated. Usually bilateral glaucoma did not come to the surgeon's notice until the disease had totally blinded one eye. In such cases the blind eye should be removed and the other should be treated by irradiation, though the results of this latter were not, he thought, very encouraging. The author thought that radiographs of the optic foramen should be more frequently carried out, as they would afford valuable diagnostic information, as well as giving a clue as to prognosis and treatment. Radiotherapy did not yet seem to have brought about many absolute cures of glioma.

Blood-Chemistry of Patients with Primary Cataracts.

Dr. Maxwell Langdon (Philadelphia) read a paper in which he pointed out that certain physical conditions accompanying lens degeneration caused also urinary changes, and he had been engaged since 1920 in an investigation of the blood-sugar and sugar-tolerance, also the blood-urea nitrogen and creatinin. Mostly his findings had been negative, and the analysis seemed to be of value only as regards sugar, several cases of potential diabetes having been discovered in which this appeared to be the only indication.

Intracapsular Extraction of Cataract.

A paper on this subject was read by Dr. A. H. H. Sinclair (Edinburgh), who showed in connexion with the paper some new instruments and explained their uses. He said the methods of intracapsular extraction practised to-day could be stated thus: (1) Dislocation and expression of the lens by pressure on the outside of the eyeball; (2) the dislocation and extraction of the lens by taking hold of its anterior capsule and removing it by traction; (3) a combination of traction and external pressure either simultaneously employed or with pressure following on forceps dislocation. He said his own method of intracapsular extraction now described was carried out with blunt forceps. The resultant vision in which the lens was removed completely came out as follows: 6/5 in two cases, 6/6 in 16, 6/9 in eight, 6/12 in one, 6/18 in one, 6/60 in one. He

explained that in nine cases the lens were not extracted complete in the grasp of the forceps. In these the vision was 6/5 in one, 6/6 in three, 6/9 in one, 6/12 in two, 6/18 in two. In his second series of 21 cases, since he had used his "expressor guard," there had been no loss of vitreous, and in this series there was only one case of iritis. The average vision in his first series was 6/11, in the second 6/7. Dr. Sinclair gave a remarkable cinematograph demonstration of the actual operation.

Late Results of Intracapsular Cataract Extraction.

Dr. Arnold Knapp (New York) related some late results of intracapsular cataract extractions in his practice. He said that criticism had been levelled against intracapsular cataract extraction because, in addition to vitreous loss in many, there was undue damage caused to the eye, the pupil was displaced, and set going degenerative changes which eventuated in damage. Some advocated retention of the posterior capsule, as it constituted an important support for the vitreous. Dr. Knapp submitted that the best answer on these points was furnished by a further examination, after a number of years, of patients on whom the intracapsular operation had been done. He did not think the ideal operation had yet been found. With this object he had followed up and re-examined as large a proportion of the 200 consecutive intracapsular cases done between 1910 and 1919 as he was able. He gave tables of results which were, on the whole, quite favourable. A small escape of vitreous did not seem to have any special significance.

Lt.-Col. H. Smith, I.M.S., said Dr. Knapp's results were very encouraging to those who thought of embarking on the intracapsular extraction of cataract, and the series reported showed that it was possible to exaggerate the seriousness of the escape of a small quantity of vitreous.

Sir Wm. Lister expressed his satisfaction that Dr. Knapp's contribution showed again that a successfully performed intracapsular extraction did wear. He had himself been astonished by the good results of the intracapsular operation as carried out by Colonel Smith, even in the bad cases, and he had himself investigated 91 cases in India. He asked ophthalmic surgeons to watch their cases in which they did the cataract operation and see what happened to them in a few years, and to base their views upon what they found.

Dr. Sinclair also considered that Dr. Knapp's series of operation results were very encouraging to those whose ambition it was to embark on this proceeding. He had not himself lost an eye after this operation in two and a half years.

Mr. D. V. Giri (Eastbourne) said that in many cases of hypermetropic cataract the vitreous was already fluid and filled with opacities, and when this was so the escape of a little vitreous even did good, as otherwise the degenerate vitreous might act as an irritant and cause further damage.

Dacryocystencleisis.

Mr. Eric A. Thomson (Beyrout) explained that this operation was intended as a substitute for dacryocystectomy, and was mostly indicated where the latter would be chosen, but hesitation was dictated by the infirmity or nervousness of the patient. The results were equally good. The operation consisted in the obliteration of the sac, canaliculi, and puncta by an inflammatory process caused by the injection of saturated corrosive sublimate aqueous solution, followed by absolute alcohol, strong tincture of iodine, alcohol again, and ether. The puncta were touched by the actual cautery as an extra precaution, and the cornea must be protected from the drugs employed. A pressure bandage and pad were kept over the region of the sac for six days.

Removal of Cataract in its Capsule.

Mr. John Hern (Darlington) contributed a paper in which he described his method of removing a cataract in its capsule, requiring the use of only two special instruments. These were: (1) An eye speculum which could be adapted to any face or either eye. A spring separated the blades, and by screw adjustments the lids could be slightly removed from the eyeball before operating. (2) A pair of forceps with entirely separate blades, fitted together by the ordinary "Smellie" lock. A preliminary iridectomy should be done, and the corneal incision should be limbal and fairly large. The chief danger was that from possible loss of vitreous, but with the lids so well under control by the special speculum there had been little trouble on this score; and he considered that the clear pupil and the impossibility of the occurrence of "after-cataract" more than compensated for this should it occur.

Lens Antigen Treatment of Cataract.

Dr. A. E. Davis (New York), in a paper with this title, said that by the use of lens antigen alone almost every case of cataract in its early incipiency could be arrested. Immature cataracts, up to 50 per cent. loss of function, in 85 per cent. of the cases could be arrested, and in more than half the cases there was improved vision. Mature senile cataracts he preferred to remove by operation. The prognosis was less favourable the later the cases were treated by lens antigen. The longest time he had had these cases under observation was four years, and the average loss of vision in the cases was about 12 per cent.

Recovery of Visual Field in Pituitary Tumours.

Dr. R. C. Davenport (London) reported two cases of pituitary tumour which were under the care of Mr. Foster Moore. Neither of them had marked glandular signs, but each showed primary optic atrophy and temporal hemianopia. In both the visual signs had been present some years, and had since been watched for three to five years. X ray examination revealed extensive bone erosion in the pituitary region in both patients. In one case one eye was blind, the vision in the other being 6/18. The whole temporal visual field was lost. The other patient had only the nasal half of the field in one eye, with an acuity of 6/12, that of the other eye being only 6/60, with only a small upper nasal section of the field remaining. The treatment of both was by irradiation of the head, directed to the pituitary region, and the fields had improved, but the visual acuity remained as before. A question which arose was as to how much the recovery might be spontaneous, and how much it was due to the shrinkage of the tumour from the application of the rays.

Cerebro-Macular Degeneration.

Dr. Gordon Holmes and Mr. Leslie Paton presented a paper on this subject. They said they had been able during recent years to examine ophthalmoscopically a number of cases of cerebro-macular degeneration of the Batten type. In most of them the retinal changes were fairly well marked when the cases came under observation. The occurrence of the disease in two members of a family led to the whole family being kept under inspection, and this resulted in the very earliest stages of the development being observed in a third member. The first noticeable change was the appearance of a small whitish area at the macula, surrounded by a reddened ring. Later, wavy radiating white streaks appeared on the retina; then the macula showed dotting, with granular pigment in and around the whitish area. The optic disc became paler and the vessels diminished in size. In the third stage the evidences of retinal atrophy spread out to the periphery, but the evidences were still most marked at the macula. Clinically, the cases were most closely related to amaurotic family idiocy.

Genesis of Myopia.

Mr. Ernest Clarke (London) examined the various inherited influences which had been suggested as the origin of myopia, and arrived, by a process of exclusion, to a confirmation of the view of Sir Arthur Keith that the origin of myopia was an inherited disorder affecting the very early growth of the sclerotic. He suggested that some bad cases of high myopia were

ment, and showed slides illustrative of the appearances seen in uveitis, retinitis proliferans, detachment of retina, asteroid hyalitis, and traumatic vitreous. In connexion with cataract extraction, Dr. Bedell said there was always a prolapse of vitreous after this operation if the posterior capsule was opened.

The Lens.—This part of the subject was dealt with by Mr. T. Harrison Butler (Birmingham). He said the lens was suspended in the eye like the hub of a bicycle and was completely surrounded by aqueous. The retro-lental space was a cleft filled with aqueous, and it disappeared in cases of degeneration of the vitreous. After the removal of cataract in the young the retro-lental space was greatly enlarged. He said that in cases of congenital dislocation of the lens the zonule might be complete, rudimentary, or absent altogether. When the lens was forcibly dislocated, the zonular lamella might peel off with the fibres of the suspensory ligament, which were not then found attached to the lens. He showed drawings illustrating detachment in lens dislocation, in glass-blower's cataract, and in an example of a shrunken lens. The lens sutures were known to constitute the sites of various kinds of cataract. The lens shagreen he regarded as due to the intimate structure of the capsule itself. He showed that an abnormal growth of the lens zones caused central cataracts, and to the varied forms of zonular or lamellar cataract. He suggested that the varied curves associated with appropriate refractive indices were so balanced that chromatic aberration was corrected.

Mr. Basil Graves dealt chiefly with the optics of these new instruments, and had a good many hints to impart on their successful use. His contribution was chiefly an epidiascope demonstration.

Miss Ida Mann spoke on the embryology of the lens and the correlation of it with slit-lamp appearances. In the first stage shown the lens was present only as an open pit in the surface ectoderm. At this stage could be seen the beginnings of the free cells, which were later seen in the cavity of the lens vesicle, the persistence of which Vogt considered was the cause of anterior axial embryonic cataract. But examination of this and succeeding stages to full term made this unlikely, as the opacities described as occurring in the adult lens were in the neighbourhood of the anterior Y-suture, while the potential cavity of the lens vesicle was immediately under the anterior lens epithelium.

Other participants in the discussion were Mr. Charles Goulden, Mr. Inglis Pollock, Mr. Gray Clegg, Dr. Feingold, Dr. Zentmayer, Dr. Finoff, Dr. McLean, and the President. The openers replied.

READING OF PAPERS.

At the afternoon session on Friday papers were read covering a wide variety of subjects. Mr. Leslie Paton and Miss Mann presented an elaborate thesis on the

Development of the Oculo-Motor Nuclei

and its bearing on the Argyll Robertson pupil reaction. They said that the break in the reflex arc which brought about the Argyll Robertson pupil probably occurred in the secondary intercalated neurone, which had its cell of origin in the anterior corpus quadrigeminum and whose axone passed down and probably bifurcated so as to link up with the third nerve nuclei on both sides. If the Edinger Westphal nuclei were concerned in the innervation of the sphincter pupillæ it was probable that the light reflex fibres were non-myelinated fibres running through the central grey matter straight to the neighbourhood of the Edinger Westphal nuclei. But Magitot contended that the Edinger Westphal nuclei could not be concerned with the control of the sphincter iridis, because in the human fœtus neither they nor any of the other anterior accessory nuclei of the third were developed at a time when the light reflex was already existent. That authority had seen the light reflex in a child which was born at the end of the fifth month, whereas the nuclei in question did not appear until the seventh month of intrauterine life. Mr. Paton suggested a reinvestigation of the embryology of the third nerve nucleus and its accessory nuclei, as that might throw light on this difficult question. A result of the examination of human embryos at various stages undertaken by one of the authors of this paper was that it seemed that the differentiation of the third nerve nucleus into its component parts commenced at a comparatively early stage, being well advanced before the end of the fifth month. Reference was made to the work of Kappers, and Mr. Paton said it could be shown that in human embryos the median nucleus appeared early, before the accessory nucleus, at a time when the swinging round of the eyes from the sides to the front of the head was taking place, while the appearance of the accessory nucleus was delayed until the first signs of differentiation of the margin of the optic cup to form an irido-ciliary region. In fœtuses of three and a half to four months the typical small cells of the accessory nuclei could be recognised, the anterior layer of the ectodermal part of the iris at the same time giving rise to the muscle-cells of the sphincter pupillæ. Thus, in both phylogeny and ontogeny the appearance of the median nucleus was associated with the possibility of convergence, and that of the Edinger Westphal nucleus with the possibility of a light reaction.

Glioma Retinæ.

Dr. J. Van der Hœve (Leiden) showed photographs of metastases of glioma retinæ in various parts of the head of a child after binocular enucleation, with the result of causing a massive disfigurement of the whole head and face. Exenteration of the orbit showed an optic nerve three to four times the normal size. The enlargement of the optic foramen he regarded as of serious prognostic import. In unilateral glaucoma the eye should be enucleated. Usually bilateral glaucoma did not come to the surgeon's notice until the disease had totally blinded one eye. In such cases the blind eye should be removed and the other should be treated by irradiation, though the results of this latter were not, he thought, very encouraging. The author thought that radiographs of the optic foramen should be more frequently carried out, as they would afford valuable diagnostic information, as well as giving a clue as to prognosis and treatment. Radiotherapy did not yet seem to have brought about many absolute cures of glioma.

Blood-Chemistry of Patients with Primary Cataracts.

Dr. Maxwell Langdon (Philadelphia) read a paper in which he pointed out that certain physical conditions accompanying lens degeneration caused also urinary changes, and he had been engaged since 1920 in an investigation of the blood-sugar and sugar-tolerance, also the blood-urea nitrogen and creatinin. Mostly his findings had been negative, and the analysis seemed to be of value only as regards sugar, several cases of potential diabetes having been discovered in which this appeared to be the only indication.

Intracapsular Extraction of Cataract.

A paper on this subject was read by Dr. A. H. H. Sinclair (Edinburgh), who showed in connexion with the paper some new instruments and explained their uses. He said the methods of intracapsular extraction practised to-day could be stated thus: (1) Dislocation and expression of the lens by pressure on the outside of the eyeball; (2) the dislocation and extraction of the lens by taking hold of its anterior capsule and removing it by traction; (3) a combination of traction and external pressure either simultaneously employed or with pressure following on forceps dislocation. He said his own method of intracapsular extraction now described was carried out with blunt forceps. The resultant vision in which the lens was removed completely came out as follows: 6/5 in two cases, 6/6 in 16, 6/9 in eight, 6/12 in one, 6/18 in one, 6/60 in one. He

explained that in nine cases the lens were not extracted complete in the grasp of the forceps. In these the vision was 6/5 in one, 6/6 in three, 6/9 in one, 6/12 in two, 6/18 in two. In his second series of 21 cases, since he had used his "expressor guard," there had been no loss of vitreous, and in this series there was only one case of iritis. The average vision in his first series was 6/11, in the second 6/7. Dr. Sinclair gave a remarkable cinematograph demonstration of the actual operation.

Late Results of Intracapsular Cataract Extraction.

Dr. Arnold Knapp (New York) related some late results of intracapsular cataract extractions in his practice. He said that criticism had been levelled against intracapsular cataract extraction because, in addition to vitreous loss in many, there was undue damage caused to the eye, the pupil was displaced, and set going degenerative changes which eventuated in damage. Some advocated retention of the posterior capsule, as it constituted an important support for the vitreous. Dr. Knapp submitted that the best answer on these points was furnished by a further examination, after a number of years, of patients on whom the intracapsular operation had been done. He did not think the ideal operation had yet been found. With this object he had followed up and re-examined as large a proportion of the 200 consecutive intracapsular cases done between 1010 and 1010 as he was able. He gave tables of results which were, on the whole, quite favourable. A small escape of vitreous did not seem to have any special significance.

Lt.-Col. H. Smith, I.M.S., said Dr. Knapp's results were very encouraging to those who thought of embarking on the intracapsular extraction of cataract, and the series reported showed that it was possible to exaggerate the seriousness of the escape of a small quantity of vitreous.

Sir Wm. Lister expressed his satisfaction that Dr. Knapp's contribution showed again that a successfully performed intracapsular extraction did wear. He had himself been astonished by the good results of the intracapsular operation as carried out by Colonel Smith, even in the bad cases, and he had himself investigated 01 cases in India. He asked ophthalmic surgeons to watch their cases in which they did the cataract operation and see what happened to them in a few years, and to base their views upon what they found.

Dr. Sinclair also considered that Dr. Knapp's series of operation results were very encouraging to those whose ambition it was to embark on this proceeding. He had not himself lost an eye after this operation in two and a half years.

Mr. D. V. Giri (Eastbourne) said that in many cases of hypermetropic cataract the vitreous was already fluid and filled with opacities, and when this was so the escape of a little vitreous even did good, as otherwise the degenerate vitreous might act as an irritant and cause further damage.

Dacryocystenclcisis.

Mr. Eric A. Thomson (Beyrout) explained that this operation was intended as a substitute for dacryocystectomy, and was mostly indicated where the latter would be chosen, but hesitation was dictated by the infirmity or nervousness of the patient. The results were equally good. The operation consisted in the obliteration of the sac, canaliculi, and puncta by an inflammatory process caused by the injection of saturated corrosive sublimate aqueous solution, followed by absolute alcohol, strong tincture of iodine, alcohol again, and ether. The puncta were touched by the actual cautery as an extra precaution, and the cornea must be protected from the drugs employed. A pressure bandage and pad were kept over the region of the sac for six days.

Removal of Cataract in its Capsule.

Mr. John Hern (Darlington) contributed a paper in which he described his method of removing a cataract in its capsule, requiring the use of only two special instruments. These were: (1) An eye speculum which could be adapted to any face or either eye. A spring separated the blades, and by screw adjustments the lids could be slightly removed from the eyeball before operating. (2) A pair of forceps with entirely separate blades, fitted together by the ordinary "Smellie" lock. A preliminary iridectomy should be done, and the corneal incision should be limbal and fairly large. The chief danger was that from possible loss of vitreous, but with the lids so well under control by the special speculum there had been little trouble on this score; and he considered that the clear pupil and the impossibility of the occurrence of "after-cataract" more than compensated for this should it occur.

Lens Antigen Treatment of Cataract.

Dr. A. E. Davis (New York), in a paper with this title, said that by the use of lens antigen alone almost every case of cataract in its early incipiency could be arrested. Immature cataracts, up to 50 per cent. loss of function, in 85 per cent. of the cases could be arrested, and in more than half the cases there was improved vision. Mature senile cataracts he preferred to remove by operation. The prognosis was less favourable the later the cases were treated by lens antigen. The longest time he had had these cases under observation was four years, and the average loss of vision in the cases was about 12 per cent.

Recovery of Visual Field in Pituitary Tumours.

Dr. R. C. Davenport (London) reported two cases of pituitary tumour which were under the care of Mr. Foster Moore. Neither of them had marked glandular signs, but each showed primary optic atrophy and temporal hemianopia. In both the visual signs had been present some years, and had since been watched for three to five years. X ray examination revealed extensive bone erosion in the pituitary region in both patients. In one case one eye was blind, the vision in the other being 6/18. The whole temporal visual field was lost. The other patient had only the nasal half of the field in one eye, with an acuity of 6/12, that of the other eye being only 6/60, with only a small upper nasal section of the field remaining. The treatment of both was by irradiation of the head, directed to the pituitary region, and the fields had improved, but the visual acuity remained as before. A question which arose was as to how much the recovery might be spontaneous, and how much it was due to the shrinkage of the tumour from the application of the rays.

Cerebro-Macular Degeneration.

Dr. Gordon Holmes and Mr. Leslie Paton presented a paper on this subject. They said they had been able during recent years to examine ophthalmoscopically a number of cases of cerebro-macular degeneration of the Batten type. In most of them the retinal changes were fairly well marked when the cases came under observation. The occurrence of the disease in two members of a family led to the whole family being kept under inspection, and this resulted in the very earliest stages of the development being observed in a third member. The first noticeable change was the appearance of a small whitish area at the macula surrounded by a reddened ring. Later, wavy radiating white streaks appeared on the retina; then the macula showed dotting, with granular pigment in and around the whitish area. The optic disc became paler and the vessels diminished in size. In the third stage the evidences of retinal atrophy spread out to the periphery, but the evidences were still most marked at the macula. Clinically, the cases were most closely related to amaurotic family idiocy.

Genesis of Myopia.

Mr. Ernest Clarke (London) examined the various inherited influences which had been suggested as the origin of myopia, and arrived, by a process of exclusion, to a confirmation of the view of Sir Arthur Keith that the origin of myopia was an inherited disorder affecting the very early growth of the sclerotic. He suggested that some bad cases of high myopia were

ment, and showed slides illustrative of the appearances seen in uveitis, retinitis proliferans, detachment of retina, asteroid hyalitis, and traumatic vitreous. In connexion with cataract extraction, Dr. Bedell said there was always a prolapse of vitreous after this operation if the posterior capsule was opened.

The Lens.—This part of the subject was dealt with by Mr. T. Harrison Butler (Birmingham). He said the lens was suspended in the eye like the hub of a bicycle and was completely surrounded by aqueous. The retro-lental space was a cleft filled with aqueous, and it disappeared in cases of degeneration of the vitreous. After the removal of cataract in the young the retro-lental space was greatly enlarged. He said that in cases of congenital dislocation of the lens the zonule might be complete, rudimentary, or absent altogether. When the lens was forcibly dislocated, the zonular lamella might peel off with the fibres of the suspensory ligament, which were not then found attached to the lens. He showed drawings illustrating detachment in lens dislocation, in glass-blower's cataract, and in an example of a shrunken lens. The lens sutures were known to constitute the sites of various kinds of cataract. The lens shagreen he regarded as due to the intimate structure of the capsule itself. He showed that an abnormal growth of the lens zones caused central cataracts, and to the varied forms of zonular or lamellar cataract. He suggested that the varied curves associated with appropriate refractive indices were so balanced that chromatic aberration was corrected.

Mr. Basil Graves dealt chiefly with the optics of these new instruments, and had a good many hints to impart on their successful use. His contribution was chiefly an epidiascope demonstration.

Miss Ida Mann spoke on the embryology of the lens and the correlation of it with slit-lamp appearances. In the first stage shown the lens was present only as an open pit in the surface ectoderm. At this stage could be seen the beginnings of the free cells, which were later seen in the cavity of the lens vesicle, the persistence of which Vogt considered was the cause of anterior axial embryonic cataract. But examination of this and succeeding stages to full term made this unlikely, as the opacities described as occurring in the adult lens were in the neighbourhood of the anterior Y-suture, while the potential cavity of the lens vesicle was immediately under the anterior lens epithelium.

Other participants in the discussion were Mr. Charles Goulden, Mr. Inglis Pollock, Mr. Gray Clegg, Dr. Feingold, Dr. Zentmayer, Dr. Finoff, Dr. McLean, and the President. The openers replied.

READING OF PAPERS.

At the afternoon session on Friday papers were read covering a wide variety of subjects. Mr. Leslie Paton and Miss Mann presented an elaborate thesis on the

Development of the Oculo-Motor Nuclei

and its bearing on the Argyll Robertson pupil reaction. They said that the break in the reflex arc which brought about the Argyll Robertson pupil probably occurred in the secondary intercalated neurone, which had its cell of origin in the anterior corpus quadrigeminum and whose axone passed down and probably bifurcated so as to link up with the third nerve nuclei on both sides. If the Edinger Westphal nuclei were concerned in the innervation of the sphincter pupillæ it was probable that the light reflex fibres were non-myelinated fibres running through the central grey matter straight to the neighbourhood of the Edinger Westphal nuclei. But Magitot contended that the Edinger Westphal nuclei could not be concerned with the control of the sphincter iridis, because in the human fœtus neither they nor any of the other anterior accessory nuclei of the third were developed at a time when the light reflex was already existent. That authority had seen the light reflex in a child which was born at the end of the fifth month, whereas the nuclei in question did not appear until the seventh month of intrauterine life. Mr. Paton suggested a reinvestigation of the embryology of the third nerve nucleus and its accessory nuclei, as that might throw light on this difficult question. A result of the examination of human embryos at various stages undertaken by one of the authors of this paper was that it seemed that the differentiation of the third nerve nucleus into its component parts commenced at a comparatively early stage, being well advanced before the end of the fifth month. Reference was made to the work of Kappers, and Mr. Paton said it could be shown that in human embryos the median nucleus appeared early, before the accessory nucleus, at a time when the swinging round of the eyes from the sides to the front of the head was taking place, while the appearance of the accessory nucleus was delayed until the first signs of differentiation of the margin of the optic cup to form an irido-ciliary region. In fœtuses of three and a half to four months the typical small cells of the accessory nuclei could be recognised, the anterior layer of the ectodermal part of the iris at the same time giving rise to the muscle-cells of the sphincter pupillæ. Thus, in both phylogeny and ontogeny the appearance of the median nucleus was associated with the possibility of convergence, and that of the Edinger Westphal nucleus with the possibility of a light reaction.

Glioma Retinæ.

Dr. J. Van der Hœve (Leiden) showed photographs of metastases of glioma retinæ in various parts of the head of a child after binocular enucleation, with the result of causing a massive disfigurement of the whole head and face. Exenteration of the orbit showed an optic nerve three to four times the normal size. The enlargement of the optic foramen he regarded as of serious prognostic import. In unilateral glaucoma the eye should be enucleated. Usually bilateral glaucoma did not come to the surgeon's notice until the disease had totally blinded one eye. In such cases the blind eye should be removed and the other should be treated by irradiation, though the results of this latter were not, he thought, very encouraging. The author thought that radiographs of the optic foramen should be more frequently carried out, as they would afford valuable diagnostic information, as well as giving a clue as to prognosis and treatment. Radiotherapy did not yet seem to have brought about many absolute cures of glioma.

Blood-Chemistry of Patients with Primary Cataracts.

Dr. Maxwell Langdon (Philadelphia) read a paper in which he pointed out that certain physical conditions accompanying lens degeneration caused also urinary changes, and he had been engaged since 1920 in an investigation of the blood-sugar and sugar-tolerance, also the blood-urea nitrogen and creatinin. Mostly his findings had been negative, and the analysis seemed to be of value only as regards sugar, several cases of potential diabetes having been discovered in which this appeared to be the only indication.

Intracapsular Extraction of Cataract.

A paper on this subject was read by Dr. A. H. H. Sinclair (Edinburgh), who showed in connexion with the paper some new instruments and explained their uses. He said the methods of intracapsular extraction practised to-day could be stated thus: (1) Dislocation and expression of the lens by pressure on the outside of the eyeball; (2) the dislocation and extraction of the lens by taking hold of its anterior capsule and removing it by traction; (3) a combination of traction and external pressure either simultaneously employed or with pressure following on forceps dislocation. He said his own method of intracapsular extraction now described was carried out with blunt forceps. The resultant vision in which the lens was removed completely came out as follows: 6/5 in two cases, 6/6 in 10, 6/9 in eight, 6/12 in one, 6/18 in one, 6/60 in one. He

explained that in nine cases the lens were not extracted complete in the grasp of the forceps. In these the vision was 6/5 in one, 6/6 in three, 6/9 in one, 6/12 in two, 6/18 in two. In his second series of 21 cases, since he had used his "expressor guard," there had been no loss of vitreous, and in this series there was only one case of iritis. The average vision in his first series was 6/11, in the second 6/7. Dr. Sinclair gave a remarkable cinematograph demonstration of the actual operation.

Late Results of Intracapsular Cataract Extraction.

Dr. Arnold Knapp (New York) related some late results of intracapsular cataract extractions in his practice. He said that criticism had been levelled against intracapsular cataract extraction because, in addition to vitreous loss in many, there was undue damage caused to the eye, the pupil was displaced, and set going degenerative changes which eventuated in damage. Some advocated retention of the posterior capsule, as it constituted an important support for the vitreous. Dr. Knapp submitted that the best answer on these points was furnished by a further examination, after a number of years, of patients on whom the intracapsular operation had been done. He did not think the ideal operation had yet been found. With this object he had followed up and re-examined as large a proportion of the 200 consecutive intracapsular cases done between 1910 and 1919 as he was able. He gave tables of results which were, on the whole, quite favourable. A small escape of vitreous did not seem to have any special significance.

Lt.-Col. H. Smith, I.M.S., said Dr. Knapp's results were very encouraging to those who thought of embarking on the intracapsular extraction of cataract, and the series reported showed that it was possible to exaggerate the seriousness of the escape of a small quantity of vitreous.

Sir Wm. Lister expressed his satisfaction that Dr. Knapp's contribution showed again that a successfully performed intracapsular extraction did wear. He had himself been astonished by the good results of the intracapsular operation as carried out by Colonel Smith, even in the bad cases, and he had himself investigated 91 cases in India. He asked ophthalmic surgeons to watch their cases in which they did the cataract operation and see what happened to them in a few years, and to base their views upon what they found.

Dr. Sinclair also considered that Dr. Knapp's series of operation results were very encouraging to those whose ambition it was to embark on this proceeding. He had not himself lost an eye after this operation in two and a half years.

Mr. D. V. Giri (Eastbourne) said that in many cases of hypermetropic cataract the vitreous was already fluid and filled with opacities, and when this was so the escape of a little vitreous even did good, as otherwise the degenerate vitreous might act as an irritant and cause further damage.

Dacryocystencleisis.

Mr. Eric A. Thomson (Beyrout) explained that this operation was intended as a substitute for dacryocystectomy, and was mostly indicated where the latter would be chosen, but hesitation was dictated by the infirmity or nervousness of the patient. The results were equally good. The operation consisted in the obliteration of the sac, canaliculi, and puncta by an inflammatory process caused by the injection of saturated corrosive sublimate aqueous solution, followed by absolute alcohol, strong tincture of iodine, alcohol again, and ether. The puncta were touched by the actual cautery as an extra precaution, and the cornea must be protected from the drugs employed. A pressure bandage and pad were kept over the region of the sac for six days.

Removal of Cataract in its Capsule.

Mr. John Hern (Darlington) contributed a paper in which he described his method of removing a cataract in its capsule, requiring the use of only two special instruments. These were: (1) An eye speculum which could be adapted to any face or either eye. A spring separated the blades, and by screw adjustments the lids could be slightly removed from the eyeball before operating. (2) A pair of forceps with entirely separate blades, fitted together by the ordinary "Smellie" lock. A preliminary iridectomy should be done, and the corneal incision should be limbal and fairly large. The chief danger was that from possible loss of vitreous, but with the lids so well under control by the special speculum there had been little trouble on this score; and he considered that the clear pupil and the impossibility of the occurrence of "after-cataract" more than compensated for this should it occur.

Lens Antigen Treatment of Cataract.

Dr. A. E. Davis (New York), in a paper with this title, said that by the use of lens antigen alone almost every case of cataract in its early incipiency could be arrested. Immature cataracts, up to 50 per cent. loss of function, in 85 per cent. of the cases could be arrested, and in more than half the cases there was improved vision. Mature senile cataracts he preferred to remove by operation. The prognosis was less favourable the later the cases were treated by lens antigen. The longest time he had had these cases under observation was four years, and the average loss of vision in the cases was about 12 per cent.

Recovery of Visual Field in Pituitary Tumours.

Dr. R. C. Davenport (London) reported two cases of pituitary tumour which were under the care of Mr. Foster Moore. Neither of them had marked glandular signs, but each showed primary optic atrophy and temporal hemianopia. In both the visual signs had been present some years, and had since been watched for three to five years. X ray examination revealed extensive bone erosion in the pituitary region in both patients. In one case one eye was blind, the vision in the other being 6/18. The whole temporal visual field was lost. The other patient had only the nasal half of the field in one eye, with an acuity of 6/12, that of the other eye being only 6/60, with only a small upper nasal section of the field remaining. The treatment of both was by irradiation of the head, directed to the pituitary region, and the fields had improved, but the visual acuity remained as before. A question which arose was as to how much the recovery might be spontaneous, and how much it was due to the shrinkage of the tumour from the application of the rays.

Cerebro-Macular Degeneration.

Dr. Gordon Holmes and Mr. Leslie Paton presented a paper on this subject. They said they had been able during recent years to examine ophthalmoscopically a number of cases of cerebro-macular degeneration of the Batten type. In most of them the retinal changes were fairly well marked when the cases came under observation. The occurrence of the disease in two members of a family led to the whole family being kept under inspection, and this resulted in the very earliest stages of the development being observed in a third member. The first noticeable change was the appearance of a small whitish area at the macula, surrounded by a reddened ring. Later, wavy radiating white streaks appeared on the retina; then the macula showed dotting, with granular pigment in and around the whitish area. The optic disc became paler and the vessels diminished in size. In the third stage the evidences of retinal atrophy spread out to the periphery, but the evidences were still most marked at the macula. Clinically, the cases were most closely related to amaurotic family idiocy.

Genesis of Myopia.

Mr. Ernest Clarke (London) examined the various inherited influences which had been suggested as the origin of myopia, and arrived, by a process of exclusion, to a confirmation of the view of Sir Arthur Keith that the origin of myopia was an inherited disorder affecting the very early growth of the sclerotic. He suggested that some bad cases of high myopia were

a manifestation of a disease of the coats of the eye, with myopia as a sequel, not as a cause.

Uveal Pigment in Diagnosis and Treatment of Sympathetic Ophthalmia.

A paper with this title was read by Dr. Alan C. Woods (Baltimore). He explained that the diagnostic tests were a complement-fixation reaction in the blood-serum against an antigen of uveal pigment and an intradermal test to determine the patient's specific hypersensitivity to uveal pigment. The treatment was based on the idea of removing the specific pigment hypersensitivity of the person by the repeated injection of small quantities of uveal pigment, which, at the same time, stimulated the production of specific antibodies. Dr. Woods's view was that this treatment was of definite value in sympathetic ophthalmia, but he did not regard it as an absolute specific. There was no reason against it being associated with other treatment. Dr. Woods said he did not think the ætiology of sympathetic ophthalmia had yet been fully demonstrated, but he considered that there was usually an allergic phase in the disease, and that uveal pigment was at least one of the factors concerned in this phase.

CONSTITUTION OF FUTURE CONVENTIONS.

A general meeting of members of the Convention took place on Thursday afternoon for the purpose of considering whether future conventions should be of an international character on a pre-war basis. After discussion a resolution was moved by Dr. Lucien Howe, and seconded by Dr. G. Ring to the following effect:—

> That this Convention of English-speaking ophthalmological societies hereby empowers its President, Mr. E. Treacher Collins, to appoint a standing committee of five, of which he shall be chairman. The duty of this committee shall be to obtain such coöperation as is possible from representatives appointed by various national ophthalmological societies in promoting matters of international ophthalmological interest, for example: (*a*) Aiding or initiating measures by international intercourse likely to prevent the dissemination of diseases of the eye and the lessening of hereditary blindness; (*b*) the establishment of uniform methods of recording results of visual tests and other matters pertaining thereto; (*c*) the interchange of ophthalmological literature; (*d*) the promotion of international ophthalmological congresses.

This resolution was adopted as well as a further resolution, proposed by Dr. Howe and seconded by Dr. Ring, thanking the English organisers for their hospitality and for the general excellence of the arrangements.

VISITS AND FUNCTIONS.

During the week members of the Convention visited a number of institutions, such as the Royal Institution, the Royal London Ophthalmic Hospital, St. Margaret's Hospital, the L.C.C. Myopia School at Islington, St. Dunstan's, the Royal Westminster Ophthalmic Hospital, the Central London Ophthalmic Hospital, the National Library for the Blind, the Royal Eye Hospital (St. George's Circus), the Royal Normal College for the Blind, and the White Oak Ophthalmia School at Swanley.

At St. Dunstan's Hostel for the training and care of war-blinded men, the visitors were received by Sir Arnold Lawson, Chairman of the Ophthalmic Advisory Board, and by Captain Ian Fraser, M.P., Chairman of the Council, who gave interesting facts and figures with regard to the success of the work at St. Dunstan's. A total of about 1800 blinded soldiers had passed through the Hostel, of whom roughly 1000 cases were due to gunshot wounds or to explosive shell or bomb; under 300 were due to actual bullet wounds. A few were the result of concussion and accident; only three injuries were attributable to bayonet wound. A tour was made of the wards, classrooms, and workshops, where the visitors had the opportunity of seeing the skill and cheery spirit shown by the blinded men.

The Convention opened with a reception at the Royal College of Surgeons of England. Sir William and Lady Lister gave a garden party at Aubrey House on Wednesday afternoon. There was a reception at the Wellcome Historical Medical Museum on Thursday evening.

An *Official Banquet* at the Guildhall terminated the proceedings of the Convention. Mr. Treacher Collins took the chair, and the company included many distinguished guests. H.R.H. the Duke of Connaught, in replying to the Loyal toasts, said that the more the English-speaking peoples worked together, the greater the prospect of peace and prosperity for the whole world. The medical people of London were to be congratulated on their hospitality to co-workers from all parts of the world. The President, in proposing the English-speaking Ophthalmological Societies, emphasised the common inspiration of the peoples represented and the common purpose of the gathering. The complete ophthalmologist, he said, was a practitioner of medicine, a surgeon, a neurologist, a physiologist, a mathematician, a physicist, and above all, a pyschologist. Sir John Parsons, replying for the Ophthalmological Society of the United Kingdom, remarked that the Society, since its foundation in 1880, had gone on from success to success, an ascent which culminated in the Convention just concluded. America, which owed much to English ophthalmology, was now repaying that debt, not in gold, but in the coinage of inspiration returned. Dr. de Schweinitz, on behalf of America, and Dr. Gordon Byers, on behalf of the Dominions, thanked their hosts for their hospitality, and laid stress on the essential unity and similarity of outlook of all the English-speaking peoples. Mr. J. H. Fisher proposed the toast of the Guests, which was responded to by Sir George Wyatt Truscott, representing the City and Corporation of London, Sir Humphry Rolleston, representing the Royal College of Physicians, and Sir John Bland-Sutton, representing the Royal College of Surgeons. Mr. E. Clarke proposed the health of the President, Mr. Treacher Collins, whose name, he said, was known and respected where ophthalmology was practised and taught.

On Saturday, delegates visited Oxford, where they lunched at Keble College, or Cambridge, where they were entertained at Trinity College.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. O'Hea is placed on the Retd. List with the rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Maj. and Bt. Lt.-Col. T. S. Coates to be Lt.-Col., vice Lt.-Col. C. G. Thomson, to retd. pay, on account of ill-health.

Temp. Capt. R. W. Markham (Dental Surg.) relinquishes his commn. on account of ill-health and retains the rank of Capt.

TERRITORIAL ARMY.

Lt.-Col. R. C. Dun, having attained the age limit, is retired and retains his rank, with permission to wear the prescribed uniform.

Lt.-Cols. G. C. E. Simpson and J. H. Ray to be Bt. Cols.

Capt. E. M. Douglas-Morris to be Maj. (Prov.).

Capt. E. M. Jenkins is retired and retains his rank.

Capt. F. E. H. Keogh to be Maj.

Lt. C. Alison resigns his commn. and retains his rank.

2nd Lt. H. E. Suter (late Middlesex Regt.) to be Lt.

Supernumerary for Service with the O.T.C.—A. S. Gough to be Lt. for service with the Medical Unit Univ. of London, O.T.C.

TERRITORIAL ARMY RESERVE OF OFFICERS.

W. M. Robertson (late R.A.) to be Lt.

ROYAL AIR FORCE.

Flight Lt. T. C. St. C. Morton is promoted to the rank of Squadron Leader.

We regret to announce the death in his seventy-sixth year of Lieutenant-General Sir Lancelotte Gubbins, formerly Director-General A.M.S.

Correspondence.

"Audi alteram partem."

IS THERE A SEASONAL PERIODICITY IN SERUM RASHES?

To the Editor of THE LANCET.

SIR,—During my last years in Glasgow a record was kept of the serum rashes which occurred in the diphtheria wards with a view to determine whether certain batches of serum gave rise to an unusually large number of rashes. Three serums were used, Burroughs Wellcome, Parke Davis, and Hoechst, these being given in different wards. After I came to London in 1914 the record was not continued sufficiently long to determine the point for which the recording was originally instituted, but the figures suggest another point which has not, so far as I know, been raised—namely, the seasonal periodicity of serum rashes.

In Table I. the monthly admissions from diphtheria with the number of rashes are given for the years 1913 and 1914 in columns 1 to 4, and the totals in columns 5 and 6. In column 7 the percentage of the rashes occurring in the different months is given, and in column 8 the expected number of rashes if the frequency of rashes were uniform throughout the year. As the figures are small, they have been collected together in the four seasons of the year in Table II.,

TABLE I.

Month.	1913. Cases.	1913. Rashes.	1914. Cases.	1914. Rashes.	Total Cases.	Total Rashes.	Percentage of rashes.	Theoretical number.
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)

Dec... ..	74	4	34	3	108	7	6·5	16·7

TABLE II.

—	Cases.	Rashes.	Percentage of rashes.	Theoretical number.
Jan.—March ..	332	58	17·5	51·5
April—June ..	252	56	22·4	39·0
July–Sept. ..	282	27	9·5	43·5
Oct.–Dec. .	336	45	14·8	52·0

in which the number of cases, the number of rashes, and the expected number of rashes are shown. When the ordinary χ^2 test of Pearson is applied to these figures it is found that χ^2 is equal to 14·8, a divergence which would only occur in three samples out of 1000 on the laws of chance. It is, therefore, strongly suggested that there is a seasonal variation in the frequency of serum rashes. This suggestion can be easily confirmed or refuted by those in charge of large hospitals. It is a point which has great importance in immunity and epidemiology. If this variation really exists it shows that susceptibility as determined by the seasonal changes in the environment may be sufficiently important to modify greatly the progress of an epidemic, so that the epidemic might even, in certain cases, depend more on the physiology of the host than on the infecting power of the organism. This seems the only conclusion, as it is very unlikely that serums stored in a cold chamber will alter in quality to any extent with the seasons of the year.

I hope this short note will result in a sufficient record of observations by those who possess the information, either to prove or disprove it.

I am, Sir, yours faithfully,
JOHN BROWNLEE, M.D., D.Sc.

National Institute for Medical Research, July 20th, 1925.

OATMEAL AND RICKETS.

To the Editor of THE LANCET.

SIR,—With regard to Prof. E. Mellanby's investigations on rickets, referred to in your issues of April 11th and May 23rd, 1925, I suggest that in view of the report by Messrs. Webster and L. Hill on "The Causation and Prevention of Rickets" (*British Medical Journal*, May 23rd, 1925, p. 956) the pro-rachitic effect of oatmeal is in all probability due to the very high percentage (5·9 per cent.) of fat which it contains, and the consequent formation by it in the intestines of insoluble calcium soaps which are excreted unabsorbed in the fæces. Prof. Mellanby himself considers that this pro-rachitic substance is "associated with the fatty acids" as it can be obtained by the saponification of oatmeal with soda and the extraction of the mixture with petrol-ether.

Percentage content of fat in—

Oatmeal*	Maize*	Barley*	Rice*	Wheat*	Wheaten flour*	Germ of wheat†	White bread†
5·9	4·3	1·6	0·3	1·7	0·9	13·1	0·45

* Feeds and Feeding, Henry (Madison, Wis., U.S.A., 1904).
† *Notter and Firth, third edition, pp. 305 and 310.*

From the table given above it will furthermore be seen that the pro-rachitic action of the cereals investigated by Prof. Mellanby (with the exception of wheat) corresponds in a striking manner to the percentage of fat which each contains. Differences in the chemical constitution of these fats may also partly account for the different rachitic values of the cereals in which they occur.

The rachitic action of wheat is somewhat anomalous; wheaten flour which contains 0·9 per cent. of fat is stated to be less rachitic than rice which contains only 0·3 per cent. of fat, yet bread made presumably from such flour, and containing approximately only half the percentage of fat of the original flour—i.e., 0·45 per cent.—was found to be markedly rachitic in action, puppies fed on large amounts of bread developing rickets "most readily"; moreover, the addition to the diet in quantity of the germ of wheaten flour which contains 13 per cent. of fat was found to interfere consistently with the proper calcification of bone. I am, Sir, yours faithfully,

J. W. TOMB.

Mines Board of Health, Asansol, Bengal, India,
June 25th, 1925.

THE DANGER OF INCOMPATIBILITY IN BLOOD TRANSFUSION.

To the Editor of THE LANCET.

SIR,—In treatment by transfusion of blood it is of the greatest importance to select a donor whose red cells are compatible with the serum of the patient. Neglect of such a precaution may entail serious symptoms and even death. Individuals who present themselves at hospitals as prospective donors may state that they belong to, say, group I. or group II. In an emergency such a statement might be accepted as true without further investigation—e.g., where the patient has recently been grouped as a precautionary measure, and if the *ascertained* group of this patient happens to be compatible with the *stated* group of the donor. Under such circumstances the transfusion might be proceeded with forthwith.

This letter is written in order to call attention to the need of not accepting too readily as actually true a statement from a donor with reference to his blood group. An example may make this clear. At a large London hospital it was decided to transfuse a patient. This patient had been grouped while in that hospital as group II. (using B. W. and Co.'s sera). A donor presented himself as available for this patient and stated that he himself was a group II., since his blood had been so grouped a fortnight previously at another large London hospital. As a precautionary measure the blood of the patient and of the donor were put up against each other, and that of the donor was also grouped by means of stock grouping sera (B. W. and Co.'s). It was then found that the donor's blood was (i.) incompatible with that of the patient, and (ii.) belonged to group III.

Had the donor's statement been accepted and the transfusion performed, a fatal result might have occurred. Such an incident suggests that the blood of patient and prospective donor should always be tested against each other. Further, the eye alone should not be depended on for detecting the presence of agglutination, but a strong lens or a microscope should be used, more especially if stock serum is used for grouping. A fatal result has occurred when the eye alone was depended on.

I am, Sir, yours faithfully,
E. L. Hunt,
Bacteriologist, St. George's Hospital, S.W. 1.
July 18th, 1925.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Wednesday, July 15th.

Custard and Egg Powders.

Mr. Walter Baker asked the Minister of Health whether he had received a copy of the report on custard and egg powders which had been presented to the Monmouthshire County Council by the President of the National Analysts' Association; and whether, in view of the fact that these powders were in the main dyed starch and that six eggs to the ton was sufficient to comply with the law, he proposed to take any action.—Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) replied: Yes, Sir, my right hon. friend has received a copy of the report. He has no power to lay down any rules as to the composition of custard and egg powders so long as they are not injurious to health.

Sanitary Inspection of Offices.

Colonel Day asked the Home Secretary if he was aware that divers Metropolitan borough councils had made representations suggesting that the sanitary officers should be empowered to inspect offices where wage-earners were employed in the same way as factories and workshops; and would he consider introducing legislation with a view to the protection which was afforded workers in factories and workshops being extended to office workers.—Mr. G. Locker-Lampson (Under Secretary for Home Affairs) replied: No such representations have been made to the Home Office, but I understand that representations to this effect have been received by the Ministry of Health from two of the Metropolitan borough councils. My right hon. friend is afraid he cannot promise any legislation in the direction suggested.

Thursday, July 16th.

Publication of Trevethin Committee Evidence.

Mr. Snell asked the Minister of Health whether Colonel Harrison, a permanent official of the Ministry of Health, was acting under instructions when, at the recent congress of the Royal Institute of Public Health, held at Brighton, he prevented Mr. Wansey Bayly, the hon. secretary of the Society for the Prevention of Venereal Diseases, from quoting evidence which was given before the Trevethin Committee, on the ground that such evidence was confidential; whether this evidence was in fact confidential; and would he undertake that permanent officials of his department, except when acting under his instructions, would not prevent valuable information on important health subjects from being given to the public by competent medical men.—Mr. Neville Chamberlain replied: No instructions in this matter were given to the officer referred to. As regards the second part of the question, I am informed that no pledge was given to witnesses before the Trevethin Committee that their evidence would be regarded as confidential and not published, but the evidence has not been published and was not available to members of the congress, and its chairman ruled that quotations from such evidence would be out of order. I am unable to accept the implication conveyed in the last part of the question.

Uninsured Persons.

Mr. Herbert Williams asked the Minister of Health the number of employed persons in this country not insured under the National Health Insurance Acts.—Mr. Neville Chamberlain replied: No precise information of the kind desired by my hon. friend is available. The number of employed persons aged 12 or over in Great Britain in 1921, according to the census of that year, was 17,403,053, of whom it is estimated that 16,432,000 were over 16, and the estimated number of persons entitled to benefits under the National Health Insurance Acts in the same year was 15,134,000. The latter figure, however, includes some persons who had ceased to be employed, and for this and other reasons it is not directly comparable with the census figure. The balance of 1,298,000, therefore, is only a rough approximation to the number of uninsured employed persons, of whom the principal groups are non-manual workers earning more than £250 a year and persons engaged in excepted employment under the Crown and local authorities and certain statutory companies.

Health Visitor's Salary.

Mr. Gerald Hurst asked the Minister of Health whether he was aware that the Dorset County Council was advertising for a health visitor at a salary of £148 a year, out of which the person appointed had to contribute £7 15*s.* a year towards the superannuation funds and to find her own bicycle; and whether, seeing that this salary, with its yearly increments, was far below the normal scale, he would draw this council's attention to the effect of its action upon the standard of trained nurses likely to be attracted into the public health service.—Mr. Neville Chamberlain replied: Yes, Sir, I am in communication with the county council on the subject.

Optical Treatment for Panel Patients.

Mr. Blundell asked the Minister of Health the difference between optical treatment, which was previously allowed to be given as an additional benefit under the Health Insurance Acts, and ophthalmic treatment, as now allowed.—Mr. Neville Chamberlain replied: The difference is that with the new definition of the benefit it has been possible to make arrangements whereby an insured person is in a position to obtain the advice of an ophthalmic specialist when it is required in the opinion of his medical practitioner. Under the previous definition it was a matter of doubt how far this could be done.

Scarlet Fever from Ice-Cream.

Colonel Day asked the Minister of Health if he was aware of the recent outbreak of scarlet fever in Portsmouth which was traceable to ice-cream made by one manufacturer in whose employ a boy assistant was found to be suffering from the disease; would he, in the interests of public health, make an order that early notice of any illness of the principals or employees of an ice-cream manufactory should be made immediately to the local medical officer of health, and that such notice should become obligatory: and would he consider the advisability of powers being vested in medical officers of health so as to allow the inspection of places where ice-cream was made, and inspection of persons occupied with the manufacture or distribution of ice-cream.—Mr. Neville Chamberlain replied: I have received a copy of the report of the medical officer of health on the outbreak referred to. Provision is already included in the Infectious Disease (Notification) Act and in regulations made by my department for the notification of all cases of any of the principal infectious diseases, and a special provision is included in a Portsmouth local Act requiring manufacturers of and dealers in ice-cream to give notice of the outbreak of any such disease amongst their employees. I doubt whether it would be practicable to enforce a regulation that all cases of illness, however slight, should be notified. With regard to the regulation of places where ice-cream and other food is prepared, many local authorities in addition to the town council of Portsmouth have obtained special local Act powers as to ice-cream.

Friday, July 17th.

The Summer-Time Bill.

The Summer-Time Bill was considered on report.

On Clause 1 (which makes Summer Time permanent and extends the period prescribed in the previous Acts),

Sir H. Cautley moved an amendment to leave out Subsection (2), the effect of which was to limit the period of Summer Time to that fixed by the existing law—i.e., from 2 o'clock on the Sunday morning following the third Saturday in April to 2 o'clock on the Sunday morning following the third Saturday in September. He said that there was no objection to the proposal to make summer time perpetual; the only point of controversy was as regarded the date on which Summer Time should begin and end. The promoters of the Bill proposed to add about a fortnight at the beginning of the period, and a fortnight or three weeks at the end, making Summer Time finish on the first Saturday in October. Although a very good case could be made that no sufficient time had elapsed since the compromise of 1922, he felt that this was a matter which should, if possible, be amicably settled. The promoter of the Bill had made an offer which he thought generous, though he (Sir H. Cautley) could not accept it as such. This offer was to give up the early part of the period leaving the commencing date as at present, provided the opponents of the Bill would agree to the full period proposed by the Bill at the end—namely, the first Saturday in October. As chairman of the Conservative Agriculture Committee, he wished to say that they would accept that compromise if the House was willing to accept it. (Hon. Members: "No.")

Dr. **Graham Little** said he wished to voice more especially the considered opinion of the medical profession inside and outside the House. Arguments in favour of the Bill seemed so overwhelming and objections so trivial that it was hard to understand why there should be any difficulty about it. This was a measure of far-reaching importance to the health and happiness of the community. It was really one of the most important Bills that had ever been before the House or the country. He would point out the profound significance of medical unanimity on this Bill. The British Medical Association in 1923 passed this resolution: "That the British Medical Association regrets that Summer Time has been curtailed this year, as it is our opinion that Summer Time is beneficial to the health of the nation." In 1921 the Society of Medical Officers of Health passed this resolution: "The Society regards the institution of Summer Time as a great benefit to the community as a whole and can find no sufficient evidence to support the view that it must prove detrimental to the health of infants and young persons." That resolution was confirmed in 1923 and 1924. In connexion with a deputation to the Home Secretary the medical officers of health brought to his notice the resolution. He (Dr. Little) had been connected with the staff of a London hospital for children, and he said without hesitation that the statements made about the difficulty of getting children to sleep was unmitigated "tosh." He urged very strongly that there should be no curtailment of the period of Summer Time.

After further discussion, the closure was moved by the promoter of the Bill (Lieut.-Colonel **Lambert Ward**), and on a division Sir H. **Cautley**'s amendment was rejected by 201 votes to 68.

An amendment in the name of Sir R. **Sanders**, providing that Summer Time should begin on the third Saturday in April instead of the first Saturday as proposed in the Bill, was then agreed to without a division.

Sir H. **Hope** moved a further amendment to fix the last Saturday in September instead of the first Saturday in October as the date of the termination of Summer Time, which after some discussion was defeated by 228 votes to 50. The Bill was then read a third time without a division.

Therapeutic Substances Bill.

Mr. **Neville Chamberlain** (Minister of Health), in moving the second reading of the Therapeutic Substances Bill (which has already passed through the House of Lords), said he believed that it would have the assent of all parties inasmuch as it was no exaggeration to say that the lives of many people would benefit from its early passage into law. It dealt with the standardisation of vaccines, sera, toxins, antitoxins, antigens, and insulin. Practically all civilised countries had an official standardisation for these various substances and as to their purity and potency—France, Germany, Italy, Spain, the United States, Norway, Sweden. Preparations which had failed to pass the test of foreign countries were liable to be imported here. It was proposed that no one should be allowed to manufacture these substances without a licence. A joint committee would be set up consisting of the Minister of Health, the Secretary for Scotland, and the Home Secretary for Northern Ireland, with power to make regulations, to prescribe standards and tests, and from time to time to make conditions. Veterinary substances were excluded except in so far as might be necessary in certain cases.

Major-General Sir R. **Luce** said in carrying this matter one stage further they had behind them medical and scientific opinion. The substances dealt with were medically roughly of three kinds. First there were those extremely difficult chemical compounds, such as salvarsan. The regulations under the Bill would help to make quite certain that these substances did not get into the hands of people who were not qualified to deal with them. He hoped that in committee it would be possible to add to the Advisory Committee a representative of the body of general practitioners who were directly responsible for the use of these substances, possibly nominated by the British Medical Association.
